Disclaimer: The mention of trade names or commercial products in this report does not constitute endorsement or recommendation for use by the Federal government.

The Arcata Fish and Wildlife Office Fisheries Program reports its study findings through two publication series. The **Arcata Fisheries Data Series** was established to provide timely dissemination of data to local managers and for inclusion in agency databases. The **Arcata Fisheries Technical Reports** publishes scientific findings from single and multi-year studies that have undergone more extensive peer review and statistical testing. Additionally, some study results are published in a variety of professional fisheries journals.

Key words: Trinity River, downstream migrant trapping, salmon, Chinook salmon, coho salmon, steelhead, abundance index, juvenile salmon, rotary screw trap.

Abstract Juvenile salmonid emigration from the mainstem Trinity River has been monitored by the Arcata Fish and Wildlife Office since 1988 with rotary screw traps used as the primary gear type since 1989. This report describes monitoring conducted from 2001 through 2005. Catch data were used to calculate abundance indices for juvenile Chinook salmon (*Oncorhynchus tshawytscha*), coho salmon (*O. kisutch*), and steelhead (*O. mykiss*) which were used to identify the duration and peak of outmigration. In addition population estimates of juvenile Chinook salmon were derived via an intensive mark-recapture procedure from 2002 through 2005. Age of outmigrants, length frequency distributions, migration rates, and hatchery contributions were also estimated. Catch data of other species are presented for sculpin (*Cottus spp.*), speckled dace (*Rhinichthys osculus*), Klamath smallscale sucker (*Catostomus rimiculus*), Pacific lamprey (*Entosphenus tridentatus*), American shad (*Alosa sapidissima*), green sturgeon (*Acipenser medirostris*), and threespine stickleback (*Gasterosteus aculeatus*), as well as for less common species captured.

Introduction

The Klamath and Trinity rivers once supported large runs of Chinook salmon (*Oncorhynchus tshawytscha*), coho salmon (*O. kisutch*), and steelhead (*O. mykiss*) that contributed to economically and culturally important tribal, ocean troll, and recreational fisheries. Declines in the Klamath Basin anadromous fish populations due to floods, water and land management, and fish harvest management (Klamath River Basin Fisheries Task Force 1991), led Congress to enact the Trinity River Basin Fish and Wildlife Restoration Act (PL 98-541) in 1984 and the Klamath River Basin Conservation

Area Fishery Restoration Program (PL 99-552) in 1986. These acts directed the Secretary of the Interior to take actions necessary to restore the fishery resources of the Klamath Basin, primarily by addressing restoration of freshwater habitat.

Past fishery investigations in the Basin have focused primarily on adult returns, due to harvest allocation and escapement objectives. Data on adult returns, however, are not adequate for monitoring restoration efforts in the Basin because adult return data are affected by ocean mortality (both juveniles entering the ocean, and adult mortality), harvest at sea, and a number of other factors. Monitoring emigrating juvenile salmonid populations in conjunction with habitat availability data and suitability studies may permit for the evaluation of restoration efforts because these studies focus on the freshwater phase, which is directly affected by instream conditions.

Intermittent juvenile salmonid investigations have been conducted in the Klamath River Basin by the U.S. Fish and Wildlife Service, Arcata Fish and Wildlife Office since 1981 (USFWS 1982). In 1988, a substantial monitoring effort was undertaken in both the mainstem Klamath and Trinity Rivers utilizing frame nets (USFWS 1989) and rotary screw traps in 1989 (USFWS 1991). The purpose of this project was to monitor the abundance, timing, hatchery contribution, and biological parameters of emigrating anadromous salmonids in the mainstem Klamath and Trinity Rivers. The effort on the Trinity River has continued since initiated in 1989 (USFWS 1991, 1992, 1994, 1998, 1999, 2001).

Information obtained from the salmonid outmigrant monitoring effort was critical in the development of salmonid outmigrant temperature components of the hydrographs recommended in the Trinity River Flow Evaluation (USFWS and Hoopa Valley Tribe 1999). One component of the restoration strategy employed by the Trinity River Restoration Program is to provide suitable water temperatures for emigrating salmonid smolts. This goal is linked to the water temperature objectives for the lower Trinity River (USFWS and Hoopa Valley Tribe 1999, Table 5.11) and the timing of smolt emigration (USFWS and Hoopa Valley Tribe 1999, Figure 5.46). Water-year specific hydrographs were developed to achieve optimum smolt emigration temperatures in normal and wetter years and marginal temperatures in dry and critically dry water years for the majority of the smolt emigration period (USFWS and Hoopa Valley Tribe 1999, Appendix K). To evaluate the influence of the modified spring hydrographs on the salmonid smolt production, including timing, hatchery/natural contribution, and the "health" of the smolts, a smolt monitoring program was implemented in the lower Trinity River. Additionally, increases in spawning and rearing habitat should result in increased production of healthier salmonids, which can be assessed through the information collected by the smolt monitoring program.

It is intended that this information will provide basic biological information that can be used by managers to evaluate the effectiveness of habitat restoration efforts, especially the new flow regimes recommended in the Record of Decision, in restoring the fishery resources of the Trinity River.

Study Area

The Klamath River is the second largest river system in California, draining about 26,000 square kilometers (km²) in California, and 14,400 km² in Oregon. The Trinity River is the largest tributary to the Klamath River, draining approximately 7,690 km² in California. Two dams, Iron Gate Dam on the Klamath River and Lewiston Dam on the Trinity River, are the upper limits of anadromous fish migration in the Basin. Two fish hatcheries, Iron Gate Hatchery (IGH) on the Klamath River and Trinity River Hatchery (TRH), were constructed to mitigate for losses of anadromous fish habitat upstream of Iron Gate and Lewiston dams.

Trinity River juvenile salmonid outmigrant trapping was conducted at the Riverdale Campground (rkm 34) near Willow Creek, California (Figure 1). This location has been used since 1991 because the channel configuration is fairly consistent from year to year, and it has private access.

Methods

Trap Design and Operation

Outmigrant sampling was conducted by deploying one to three 2.44 m diameter rotary screw traps at the trapping site. River conditions ultimately dictated when traps were deployed. Depending on river conditions, an effort was made to place rotary traps in the river as early in the spring as possible so that portions of the coho salmon and steelhead smolt outmigration could be sampled, and prior to the emigration of age-0 Chinook salmon so that emigration patterns and the relative abundance of natural and hatchery Chinook salmon could be evaluated.

Traps were anchored with 0.64 cm diameter aircraft cable to large trees or a series of steel fence stakes. One or two 0.1 x 0.15 x 6.0 m (4"x6"x10') beams were used to push the trap out from the bank. Cone revolutions were used to determine where and when the trap could be operated without inducing unnecessary risk to the trap. Traps were fished on the edge of the thalweg during high river discharge, and incrementally moved back into the thalweg as river discharge decreased. When deployed, the bottom of the cone was generally <1 m from the stream bottom. A sample day was defined as the time period between the setting of the trap one day and removal of captured fish approximately 24 hours later. This period encompassed all night hours, when the majority of juvenile salmonids emigrate. Trap checks usually occurred during late morning or early afternoon. During peak emigration periods, fish were removed from traps several times during the sampling period with the frequency dictated by water temperatures, fish numbers, and mortality rates.

Daily trap catch data were summarized by Julian week (JW), with the first day of JW 1 commencing on the first day of the year (Table 1). All JWs are seven days in length except the last JW of the year and the 9th JW during leap years, which are both eight days in length.

Water Flow and Temperature Measurements

Normal cone operating depth was 1.07 m. Daily velocity measurements were taken directly in front of the cone as follows: the submerged portion of the cone was divided into three cells (right, center, left); within each cell, velocity was measured at 0.2 and 0.8 of the cone operating depth for 60 seconds using a General Oceanics® digital flowmeter (Model 2030) (General Oceanics, Inc. 1983). Mean water velocity (ft/s) was calculated for each cell. Each cell area (ft²) was calculated, then multiplied by its corresponding mean water velocity (ft/s). The values for each cell were summed, yielding an estimate of volume of river discharge sampled (Qs) in cubic feet per second (ft³/s). Discharge data from U.S. Geological Survey Water Resource gauge station at Hoopa (#11-530000 at rkm 19.9) on the Trinity River was used as a surrogate measure of mean daily river discharge (Q) at the trap site. It was assumed that there was no significant difference between river discharge at this gauging station and the trap location.

Water temperature data were collected using an Onset Stow Away Tidbit® temperature logger attached to the outside bottom edge of each traps live box. Temperature was recorded once per hour for the entire sampling season. Mean daily river temperatures were calculated by averaging over 24-hour periods.

Biological Sampling Procedures

All juvenile fish captured were anesthetized with tricaine methanesulfonate (MS-222) prior to processing. Up to 30 individuals of each species and age class (based on size) were randomly subsampled (biosampled) from the daily catch. Biosampled salmonids were measured to the nearest mm fork length (FL), weighed by volumetric displacement (fish over 100 mm) in 2001, weighed by digital scale in 2002-2005, and examined for external marks (stains, fin clips, tattoos), and physical irregularities. All captured salmonids that were not biosampled were tallied by species, age and examined for external marks.

All anesthetized fish not retained were allowed to resuscitate in buckets of ambient river water before being released downstream of the trap. NovAqua® water conditioner was added to recovery buckets to help protect fish during handling, minimize infection, reduce stress and aid in recovery. Adult salmonids were not anesthetized. Fork lengths of adult salmonids were either measured or approximated before release. Any salmonid mortality in the live box was checked for a fin clip and, if included in the subsample, measured. If a salmonid escaped during netting or handling before it could be identified to species or checked for a hatchery mark (i.e. fin or maxillary clip), it was counted in the sample tally as an "unknown". Based on the probability of occurrence, unknown fish were redistributed into the most likely marked or unmarked species categories.

When present, daily subsamples of marked hatchery Chinook salmon were collected. A missing adipose fin (ad-clip) was the external marker depicting Chinook salmon with a coded wire tag (CWT) embedded in the snout. A maximum of five ad-clipped Chinook salmon from each trap were collected daily and sacrificed for subsequent CWT retrieval. Collected fish were stored in a freezer until time of dissection. Occasionally, ad-clipped fish were also collected for disease sampling, after which the CWT's were removed.

Juvenile Chinook salmon were classified as age-0 (young-of-year) or age-1, based on size and date of capture. Coho salmon were classified as either age-0 or age-1; the latter of which were much larger in size, silvery, and lacked distinct parr marks. Steelhead were classified by age based on length-to-age analysis of scales collected from a subsample of steelhead captured. Analysis of scale samples collected from unmarked steelhead over the sampling season provided length-to-age relationships. Un-aged steelhead were assigned an age based on the length-to-age relationship derived from aged samples.

Fish other than Chinook salmon, coho salmon, or steelhead were considered non-target species. Non-target fishes captured were identified to species (or genus in some cases), enumerated, and up to 30 specimens of each species were measured to FL. Total length (TL) was measured on species without a forked caudal fin.

Hatchery and Natural Stocks Estimate

Captured Chinook salmon, coho salmon, and steelhead were categorized as being either of hatchery or natural origin based on external marks, coded wire tag data, and hatchery release data provided by TRH. Hatchery release strategies for Chinook salmon consist of fingerling (age-0) releases in the spring and yearling (age-1) releases in the fall. These

two distinct release periods prompted the division of the trapping season into spring and fall monitoring periods. The spring monitoring period was designated as JW 1 through 39 and the fall period JW 40 through 52. Hatchery reared steelhead and coho salmon are typically volitionally released as smolts or yearling-plus (age-1) in early spring.

Chinook Salmon

All collected ad-clipped Chinook salmon were passed through a magnetic field detector manufactured by Northwest Marine Technology® to determine the presence or absence of a CWT. The snout of each fish that registered positive for a tag was dissected until the CWT was recovered. If the tag was not recovered, the fish was considered an ad-clipped fish that had shed its tag. Recovered tags were decoded using a dissection microscope. Coded Wire Tag recoveries were summed by specific CWT code for each JW.

The number of CWT fish captured for each code was estimated by multiplying the number of CWT's recovered by an expansion factor (E) which accounts for all subsampling, CWT's that were lost during dissection, and unreadable tags. The expansion factor (E) was calculated using the formula:

$$E = (C/MS)(AD/H)(T/TR)$$

- Where: C = Total # of Chinook salmon captured,
- MS = Number of Chinook salmon examined for ad-clips,
- AD = Number of ad-clipped Chinook salmon observed,
- H = Number of ad-clipped Chinook salmon collected,
- T = Number of collected ad-clipped Chinook salmon with a CWT,
- TR = Total number of CWT's recovered and decoded after processing.

To account for unmarked hatchery fish in the catch over a JW, the expanded estimates for each CWT code were multiplied by a production multiplier (PM) specific to each CWT code. Each PM was calculated from hatchery release data (Pacific States Marine Fisheries Commission 2006), using the following formula:

$$PM = \frac{\# \text{ Tagged} + \# \text{ Poor Tagged} + \# \text{ Unmarked}}{\# \text{ Tagged}}$$

- Where: # Tagged = The actual number of ad-clipped Chinook salmon released with a CWT,
- # Poor Tagged = The number of ad-clipped Chinook salmon that were tagged and shed the tag (No-Tags),
- # Unmarked = The number of unmarked Chinook salmon in a release group.

The estimated contribution of hatchery Chinook salmon attributable to a specific CWT code for a given JW, was calculated by the following formula:

$$\# \text{ Hatcherycode}_i = (\# \text{ recoveredcode}_i) * (E_{\text{JW}}) * (\text{PMcode}_i)$$

The total weekly estimated hatchery contribution to the catch was the sum of all estimated hatchery Chinook salmon attributable to CWT codes. The weekly contribution of naturally produced Chinook salmon to the catch was estimated by subtracting the estimated hatchery contribution from the total weekly catch. Occasionally, the daily estimated hatchery contribution exceeded the total daily catch. In these instances, the estimated hatchery contribution was limited to the actual daily catch.

Towards the end of each emigration period, when catch rates were low, it is possible that juveniles of hatchery origin were captured but not represented by ad-clipped fish. If no hatchery fish captured within a given time period were marked, the hatchery contribution for that period could not be differentiated from the natural component. Thus, all fish captured during that period were considered of natural origin. The hatchery and natural stock estimates assume no differential mortality between tagged and untagged fish of the same release group, equal vulnerability to capture, and accurate estimates of the numbers of marked, unmarked, and poor tagged fish released from the hatchery. The estimate does not account for ad-clipped or non-ad-clipped hatchery fish removed from the river upstream during other juvenile monitoring operations.

Coho Salmon

All hatchery coho salmon released from TRH were marked with a right-maxillary clip (max-clip). The weekly contribution of naturally produced coho salmon to the catch was estimated by subtracting the catch of marked hatchery fish from the total catch.

Steelhead

All hatchery steelhead released from TRH were marked with an ad-clip and right-maxillary clip. The weekly contribution of naturally produced steelhead to the catch was estimated by subtracting the catch of marked hatchery fish from the total catch.

Abundance Index

A weekly abundance index for each age class of Chinook salmon, coho salmon, and steelhead was estimated for each JW based on catch-effort data. Daily abundance indices (Index_{DC}) for each species and development stage were calculated by the following equation:

$$\text{Index}_{\text{DC}} = \text{Catch}_{\text{DC}} / (Q_{\text{C}}/Q)$$

Where: Catch_{DC} = Sum of daily catch of a species from all traps
 Q_{C} = Sum of discharge sampled (ft^3/s) by all traps
 Q = Mean daily river discharge (ft^3/s)

Weekly abundance indices ($\text{Index}_{\text{CJW}_i}$) were calculated for each JW using the following equation:

$$\text{Index}_{\text{CJW}_i} = \sum \text{Index}_{\text{DC}} ((n_{t_i} * (\# \text{ days in JW}_i)) / (\sum \text{TD}_i))$$

Where: n_{t_i} = Number of traps in operation at site by week
 TD_i = Sum of the days sampled by all traps during a given JW

The estimated proportion of hatchery produced fish, based on catches of marked fish and marking rates, were used to apportion the abundance indices into production attributable to hatchery or natural production. The usefulness of this index as an estimator of abundance is contingent upon the assumptions that catch rates are directly proportional to the percentage of river flow sampled and that individuals from a given species are equally susceptible to capture. The abundance index is not intended to represent a population estimate, but is used to compare relative abundance between weeks during the trapping season, and between years.

Migration Rate

Initial migration rates for hatchery produced salmonids were estimated by dividing the distance (rkm) traveled by the number of days elapsed between the initial hatchery release date and initial capture date for specific CWT codes or marked fish. Due to potential delays in outmigration during volitional releases, mean migration rates were not calculated for volitional release groups.

Population Estimation

When capture numbers were adequate at the Willow Creek trap site (generally after TRH releases), an intensive mark-recapture sampling technique was employed to generate population estimates for combined natural and hatchery age-0 Chinook salmon. Population estimates were generated using the modified 1-site version of the Rawson model as described by Carlson et al. (1998), stratified by Julian Week. Catch from non-mark-recapture periods were not included in population totals; therefore, the estimates will be underestimates of true population size sampled during the entire trapping period.

Population estimates were not calculated for coho salmon and steelhead because too few steelhead and coho salmon were captured to generate reasonable population estimates.

Mark-Recapture Technique

A mark unique to each sampling week was applied to anesthetized individuals utilizing a BMX 1000 POW'R-Ject marking unit with photonic marking formula manufactured by NewWest Technologies®. The mark was made by subcutaneously injecting the photonic solution at the base of various fins specific to the color and fin mark designated for that week. After marking, the fish were allowed to recover in containers filled with river water that was aerated and iced to remain within 3°F of ambient river temperatures.

Upon recovery, marked fish were immediately transported upstream 0.4 km by boat and

released into a large, still pool to mix with the population that had yet to pass the sampling site. Recaptures were identified and recorded during normal trapping operations, but were excluded from the catch for that day.

Results

Sampling Season Overview

Trapping duration at the Willow Creek trap site was determined both by river conditions and funding levels. In years when the project was fully funded, trapping was generally conducted from early spring to late fall (Table 2). In 2005 the project was funded only to operate during the spring emigration period.

Table 2. Period and duration of spring and fall monitoring from 2001 through 2005 and trapping rate at the Trinity River rotary screw traps near Willow Creek (rkm 34), California, operated by the United States Fish and Wildlife Service, Arcata Fish and Wildlife Office and the Yurok Tribal Fisheries Program.

Year	Start-End Dates	Spring Fall	Number Of Traps	Days Trapped	Total Days Possible	Trapping Rate (%)

2001

Juvenile salmonid monitoring on the Trinity River at Willow Creek began April 10th and spanned 134 days during spring of 2001, and 13 days during fall of 2001. The Willow Creek Traps effectively fished for 147 days (69.7% of the 211 possible trap days) in the 2001 monitoring period (Table 2). Consistent daily data collection was disrupted (flawed set) intermittently by large woody debris and mechanical difficulties, but sampling occurred during each of the Julian Weeks during the sampling period.

Maximum daily discharge during the 2001 sampling period, as recorded at Hoopa, California US Geological Survey Water Resource gauge station #11-530000 was 5,090 ft³/s and minimum daily discharge was 509 ft³/s (Figure 2).

2002

Beginning in 2002, the AFWO and YTFP began a cooperative trapping effort at the Willow Creek trap site. This involved the installation of a second trap at the site to increase catches needed to generate mark-recapture population estimates.

Juvenile salmonid monitoring on the Trinity River at Willow Creek began March 15 and spanned 200 days during spring of 2002, and 47 days during fall of 2002. The Willow Creek Traps effectively fished for 247 days (98.0% of the 252 possible trap days) in the 2002 monitoring period (Table 2). Consistent daily data collection was disrupted (flawed set) intermittently by large woody debris and mechanical difficulties, but sampling occurred during each of the Julian Weeks during the sampling period.

Maximum daily discharge during the 2002 sampling period, as recorded at Hoopa, California US Geological Survey Water Resource gauge station #11-530000 was 7,710 ft³/s and minimum daily discharge was 499 ft³/s (Figure 2).

2003

In 2003, the AFWO and YTFP continued a cooperative trapping effort at the Willow Creek trap site. This involved the installation of two traps at the site to increase catches to facilitate mark-recapture population estimates.

Juvenile salmonid monitoring on the Trinity River at Willow Creek began March 5 and spanned 186 days during spring of 2003, and 52 days during fall of 2003. The Willow Creek Trap effectively fished for 238 days (90.8% of the 262 possible trap days) in the 2003 monitoring period (Table 2). Consistent daily data collection was disrupted (flawed set) intermittently by large woody debris and mechanical difficulties; sampling did not occur during Julian Week 18 due to high flows, but sampling occurred in all other Julian Weeks during the sampling period.

Maximum daily discharge during the 2003 sampling period, as recorded at Hoopa, California US Geological Survey Water Resource gauge station #11-530000 was 19,900 ft³/s and minimum daily discharge was 564 ft³/s (Figure 2).

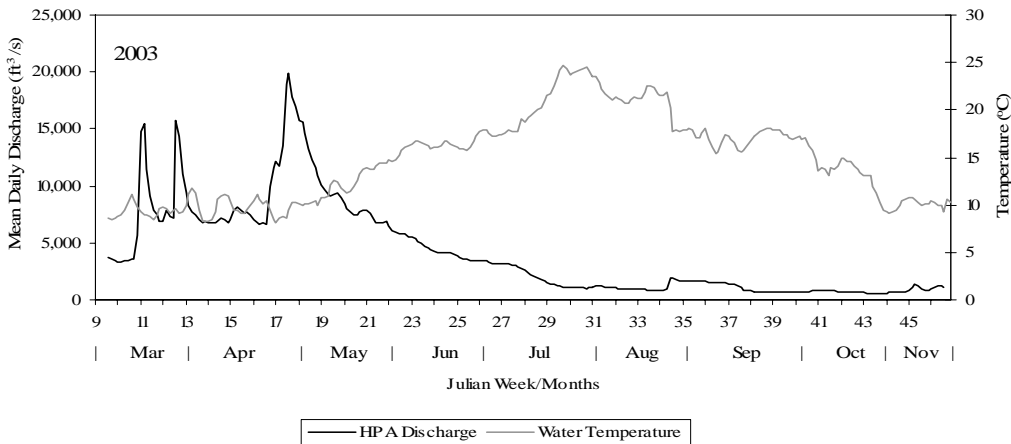

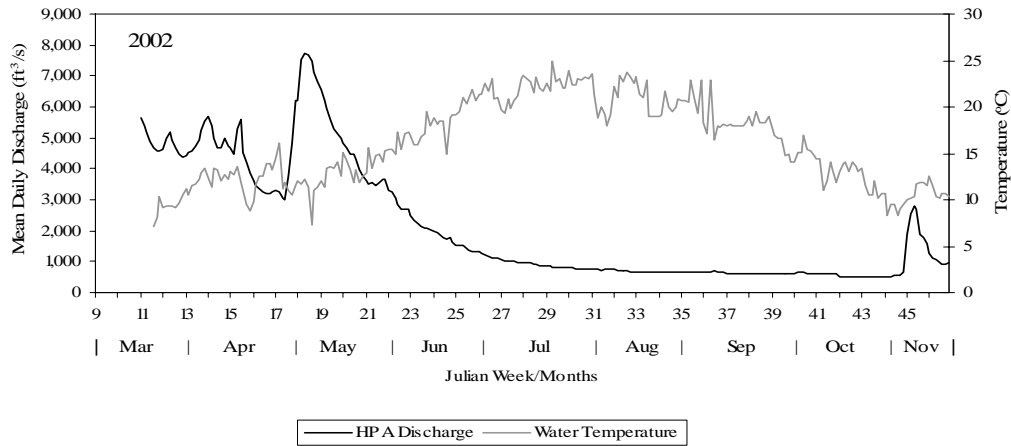

Figure 2. Mean daily discharge (ft³/s) as recorded at Hoopa, California (US Geological Survey Water Resource gauge station #11-530000) and mean daily river temperature at the Trinity River rotary screw traps near Willow Creek (rkm 34), California, 2001-2005.

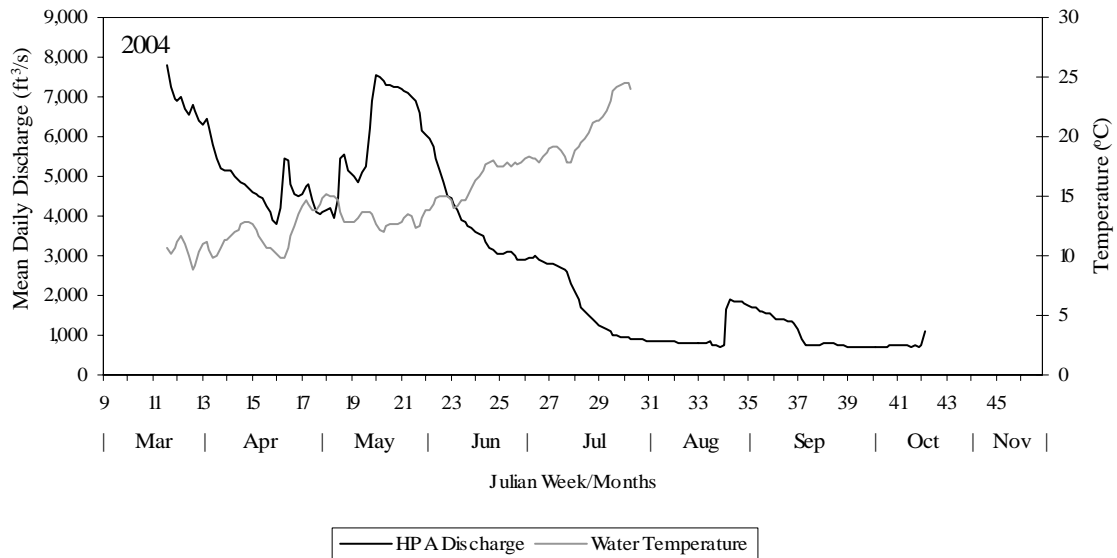

Figure 2 (continued). Mean daily discharge (ft³/s) as recorded at Hoopa, California (US Geological Survey Water Resource gauge station #11-530000) and mean daily river temperature at the Trinity River rotary screw traps near Willow Creek (rkm 34), California, 2001-2005.

2004

In 2004, the AFWO and YTFP continued a cooperative trapping effort at the Willow Creek trap site. This involved the installation of a third trap at the site to increase catches to facilitate mark-recapture population estimates.

Juvenile salmonid monitoring on the Trinity River at Willow Creek began March 19 and spanned 196 days during spring of 2004, and 17 days during fall of 2004. The Willow

Creek Traps effectively fished for 213 days (99.1% of the 215 possible trap days) in the 2004 monitoring period (Table 2). Consistent daily data collection was disrupted (flawed set) intermittently by large woody debris and mechanical difficulties, but sampling occurred during each of the Julian Weeks during the sampling period.

Maximum daily discharge during the 2004 sampling period, as recorded at Hoopa, California US Geological Survey Water Resource gauge station #11-530000 was 7,790 ft³/s and minimum daily discharge was 700 ft³/s (Figure 2).

2005

In 2005, the AFWO and YTFP continued a cooperative trapping effort at the Willow Creek trap site. This involved the installation of three traps at the site to increase catches to facilitate mark-recapture population estimates.

Juvenile salmonid monitoring on the Trinity River at Willow Creek began March 6 and spanned 168 days during spring of 2005, and 0 days during fall of 2005. The Willow Creek Traps effectively fished for 168 days (92.3% of the 182 possible trap days) in the 2005 monitoring period (Table 2). Consistent daily data collection was disrupted (flawed set) intermittently by large woody debris and mechanical difficulties; sampling did not occur during Julian Week 13 due to high flows, but sampling occurred in all other Julian Weeks during the sampling period.

Maximum daily discharge during the 2005 sampling period, as recorded at Hoopa, California US Geological Survey Water Resource gauge station #11-530000 was 29,300 ft³/s and minimum daily discharge was 843 ft³/s (Figure 2).

Catch Totals

Chinook salmon

Variations in yearly catch totals (Table 3) are affected not just by year-class strength in a given year, but also trapping duration/efficiency, and variations in timing of the Chinook salmon emigration period. In addition, TRH releases two large groups of Chinook salmon, one in May/June and one in October; in some years, limited or no sampling occurred during October so catch numbers would be affected due to the shorter sampling period.

Trinity River Hatchery released between 3.1 and 3.3 million age-0 Chinook salmon in the spring of 2001 through 2005 (Table 4). Spring releases included ad-clipped Coded Wire Tagged groups, representing 23.7 to 24.8% of released Chinook salmon. The TRH released between 1.3 and 1.4 million age-1 Chinook salmon in the fall of 2001 through 2005 (Table 4). Fall releases included ad-clipped Coded Wire Tagged groups, representing 23.4 to 24.9% of released Chinook salmon.

Table 3. Age-0 Chinook salmon catch totals for 2001 through 2005 at the Trinity River rotary screw traps near Willow Creek (rkm 34), California, operated by the United States Fish and Wildlife Service, Arcata Fish and Wildlife Office and the Yurok Tribal Fisheries Program. Hatchery and Natural catches are estimated from coded wire tag expansions.

Year	Spring Fall	Days trapped	Age-0 Chinook salmon			
			Hatchery	Natural	Total	% Hatchery
2001	Spring	134	8,335	27,962	36,297	23.0
	Fall	13	140	11	151	92.7
2002	Spring	200	19,814	35,332	55,154	35.9
	Fall	47	11,172	380	11,552	96.7
2003	Spring	186	5,523	4,760	10,283	53.7

2005	Spring	3,165,519	23.7	6/1-6/8
2005	Fall	1,391,122	23.4	10/3-10/11

2001

Spring monitoring was conducted 134 days during 2001 (Table 3). Catches of Chinook salmon were predominately natural fish with a catch of 27,962 comprising 77.0% of the total spring catch (Appendix 1). A total of 8,335 hatchery fish were captured during the spring monitoring period, comprising 23.0% of the total spring catch. While extended rearing of Chinook salmon over the winter is uncommon, occasional Chinook salmon that overwintered in the river are captured the following spring. One yearling Chinook salmon (not included in the totals presented above) that overwintered was captured during spring monitoring.

Fall monitoring was conducted 13 days during 2001 (Table 3). During the fall season the number of natural Chinook salmon captured totaled 11, representing 7.3% of the total fall Chinook salmon catch. Fall catches included 140 hatchery Chinook salmon, representing 92.7% of the total fall catch.

2002

Spring monitoring was conducted 200 days during 2002 (Table 3). Catches of Chinook salmon were predominately natural fish with a catch of 35,332 comprising 64.1% of the total spring catch (Appendix 2). A total of 19,814 hatchery fish were captured during the spring monitoring period, comprising 35.9% of the total spring catch. Eight yearling Chinook salmon (not included in the totals presented above) that overwintered were captured during spring monitoring.

Fall monitoring was conducted 47 days during 2002 (Table 3). During the fall season the number of natural Chinook salmon captured totaled 380, representing 3.3% of the total fall Chinook salmon catch. Fall catches included 11,172 hatchery Chinook salmon, representing 96.7% of the total fall catch.

2003

Spring monitoring was conducted 186 days during 2003 (Table 3). Catches of Chinook salmon were predominately hatchery fish while natural fish, with a catch of 4,760, comprised 46.3% of the total spring catch (Appendix 3). A total of 5,523 hatchery fish were captured during the spring monitoring period, comprising 53.7% of the total spring catch. Sixteen yearling Chinook salmon (not included in the totals presented above) that overwintered were captured during spring monitoring.

Fall monitoring was conducted 52 days during 2002 (Table 3). During the fall season the number of natural Chinook salmon captured totaled 214, representing 3.7% of the total fall Chinook salmon catch. Fall catches included 5,616 hatchery Chinook salmon, representing 96.3% of the total fall catch.

2004

Spring monitoring was conducted 196 days during 2002 (Table 3). Catches of Chinook salmon were predominately natural age-0 fish with a catch of 7,728, comprising 75.6% of the total spring catch (Appendix 4). A total of 2,488 hatchery fish were captured during the spring monitoring period, comprising 24.4% of the total spring catch. Twenty yearling Chinook salmon (not included in the totals presented above) that overwintered were captured during spring monitoring.

Fall monitoring was conducted 17 days during 2004 (Table 3). During the fall season the number of natural age-0 Chinook salmon captured totaled 1,475, representing 17.9% of the total fall Chinook salmon catch. Fall catches included 6,749 hatchery Chinook salmon, representing 82.1% of the total fall catch.

2005

Spring monitoring was conducted 168 days during 2005 (Table 3). Catches of Chinook salmon were predominately age-0 natural fish with a catch of 37,289, comprising 75.4% of the total spring catch (Appendix 5). A total of 12,179 hatchery fish were captured during the spring monitoring period, comprising 24.6% of the total spring catch. Three yearling Chinook salmon (not included in the totals presented above) that overwintered were captured during spring monitoring.

Fall monitoring was not conducted during 2005.

Coho Salmon

Coho salmon smolts and young-of-year were primarily captured early in the trapping season, between early March (JW 10) and late June (JW 26). Natural fish were comprised of age-0 and age-1 fish, while hatchery coho were all age-1 (Table 5). Trinity River Hatchery released yearling coho salmon during March of each of the years sampled (Table 6). All hatchery coho salmon were marked with a maxillary-clip.

Table 5. Spring and fall monitoring natural (N) age-1, hatchery (H) age-1 and natural age-0 coho salmon catch totals and percentages, captured at the Trinity River rotary screw traps near Willow Creek (rkm 34), California, 2001-2005.

Year	Days Trapped	Coho Salmon				% of Total		
		N 1	H 1	N 0	Total	% N 1	% H 1	% N 0
2001	147	53	314	150	517	10.3	60.7	29.0
2002	247	575	858	1,385	2,818	20.4	30.5	49.1
2003	238	117	141	661	919	12.7	15.3	72.0
2004	213	67	506	141	714	9.4	70.9	19.7
2005	168	51	317	1,760	2,128	2.4	14.9	82.7

Table 6. California Department of Fish and Game, Trinity River Hatchery coho salmon releases, 2001-2005.

Year	Release Dates	Number Released
2001	3/15/01-3/22/01	513,334
2002	3/15/02-3/22/02	530,285
2003	3/17/03-3/19/03	415,954
2004	3/15/04-3/17/04	517,335
2005	3/15/05-3/17/05	520,888

2001

Catches of coho salmon during spring of 2001 were predominately hatchery age-1 fish with a catch of 314, comprising 60.7% of the total spring catch (Table 5). A total of 53 natural age-1 and 150 natural age-0 coho salmon were captured during the spring

monitoring period, comprising 10.3% and 29.0%, respectively, of the total spring catch. No coho salmon were captured during the fall season of 2001.

2002

Catches of coho salmon during spring of 2002 were predominately natural age-0 fish with a catch of 1,382, comprising 46.2% of the total spring catch (Table 5). A total of 573 natural age-1 and 858 hatchery age-1 coho salmon were captured during the spring monitoring period, comprising 25.2% and 28.7%, respectively, of the total spring catch.

Five coho salmon were captured during the fall season of 2002, 3 natural age-0 and 2 natural age-1 coho salmon.

2003

Catches of coho salmon during spring of 2003 were predominately natural age-0 fish with a catch of 660, comprising 71.9% of the total spring catch (Table 5). A total of 117 natural age-1 and 141 hatchery age-1 coho salmon were captured during the spring monitoring period, comprising 12.7% and 15.4%, respectively, of the total spring catch.

One natural age-0 coho salmon was captured during the fall season of 2003.

2004

Catches of coho salmon during spring of 2004 were predominately hatchery age-1 fish with a catch of 506, comprising 70.9% of the total spring catch (Table 5). A total of 67 natural age-1 and 141 natural age-0 coho salmon were captured during the spring monitoring period, comprising 9.4% and 19.7%, respectively, of the total spring catch.

No coho salmon were captured during the fall season of 2004.

2005

Catches of coho salmon during spring of 2005 were predominately natural age-0 fish with a catch of 1,760, comprising 82.7% of the total spring catch (Table 5). A total of 51 natural age-1 and 317 hatchery age-1 coho salmon were captured during the spring monitoring period, comprising 2.4% and 14.9%, respectively, of the total spring catch.

Fall monitoring was not conducted during 2005.

Steelhead

Steelhead were comprised of natural age-0, age-1 and age-2+ (age-2 and age-3) fish, while hatchery steelhead were all age-1 (Table 7). Trinity River Hatchery released yearling steelhead during March of each of the years sampled (Table 8). All hatchery steelhead were marked with an adipose-clip.

Table 7. Steelhead catch numbers and percentages, captured at the Trinity River rotary screw traps, near Willow Creek (rkm 34), California, 2001-2005.

Year	Season	Steelhead				Total	% of Total			
		Age0	Age1	Age2+	Hat		Age0	Age1	Age2+	Hat

Table 8. California Department of Fish and Game, Trinity River Hatchery steelhead releases, 2001-2005.

Year	Release Dates	Number Released
2001	3/15/01-3/22/01	816,172
2002	3/15/02-3/22/02	624,631
2003	3/17/03-3/19/03	867,618
2004	3/15/04-3/25/04	794,227
2005	3/15/05-3/15/05	792,861

2001

Catches of steelhead during spring of 2001 were predominately hatchery age-1 fish with a catch of 400, comprising 29.2% of the total spring catch (Table 7). A total of 393 natural age-1, 372 natural age-2+, and 203 natural age-0 steelhead were captured during the spring monitoring period, comprising 28.7%, 27.2% and 14.8%, respectively, of the total spring catch.

Eight natural steelhead were captured during the fall season of 2001 fish (Table 7).

2002

Catches of steelhead during spring of 2002 were predominately natural age-0 fish with a catch of 2,491, comprising 62.8% of the total spring catch (Table 7). A total of 577 natural age-1, 128 natural age-2+, and 772 hatchery steelhead were captured during the spring monitoring period, comprising 14.5%, 3.2% and 19.5%, respectively, of the total spring catch.

One-hundred and four natural steelhead were captured during the fall season of 2002 (Table 7).

2003

Catches of steelhead during spring of 2003 were predominately natural age-0 fish with a catch of 2,122, comprising 82.4% of the total spring catch (Table 7). A total of 252 natural age-1, 43 natural age-2+, and 158 hatchery steelhead were captured during the spring monitoring period, comprising 9.9%, 1.7% and 6.1%, respectively, of the total spring catch.

Sixty-five steelhead were captured during the fall season of 2003, all but one were natural fish (Table 7).

2004

Catches of steelhead during spring of 2004 were predominately natural age-1 fish with a catch of 828, comprising 42.4% of the total spring catch (Table 7). A total of 371 natural age-0, 434 natural age-2+, and 318 hatchery steelhead were captured during the spring monitoring period, comprising 19.0%, 22.2% and 16.3%, respectively, of the total spring catch.

Four natural steelhead were captured during the fall season of 2004 (Table 7).

2005

Catches of steelhead during spring of 2005 were predominately natural age-0 fish with a catch of 840, comprising 55.9% of the total spring catch (Table 7). A total of 460 natural age-1, 69 natural age-2+, and 134 hatchery steelhead were captured during the spring monitoring period, comprising 30.6%, 4.6% and 8.9%, respectively, of the total spring catch.

Fall monitoring was not conducted during 2005.

Non-Target Species

Non-salmonid fish species captured at the Willow Creek trap site were enumerated and measured during both spring and fall monitoring periods.

2001

A total of 867 non-target fishes were captured during 2001 (Table 9). Klamath smallscale sucker (*Catostomus rimiculus*) was the most numerous non-target species. Other abundant species included threespine stickleback (*Gasterosteus aculeatus*), speckled dace (*Rhinichthys osculus*), and Pacific lamprey (*Entosphenus tridentatus*) (Table 9).

Table 9. Catch totals of non-target fish species captured at the Trinity River rotary screw trap, near Willow Creek (rkm 34), California, 2001.

Common Name	Scientific Name	Catch (n)
Klamath smallscale sucker	<i>Catostomus rimiculus</i>	251
Threespine stickleback	<i>Gasterosteus aculeatus</i>	229
Speckled dace	<i>Rhinichthys osculus</i>	222
Pacific lamprey	<i>Entosphenus tridentatus</i>	87
Sculpin species	<i>Cottus spp.</i>	55
American shad	<i>Alosa sapidissima</i>	13
Sockeye salmon	<i>Oncorhynchus nerka</i>	5
Brown trout	<i>Salmo trutta</i>	3
Golden shiner	<i>Notemigonus crysoleucas</i>	2
Season Total		867

2002

A total of 10,758 non-target fishes were captured during 2002 (Table 10). Klamath smallscale sucker were the most numerous non-target species, followed by American shad (*Alosa sapidissima*), Pacific lamprey, and speckled dace.

Table 10. Catch totals of non-target fish species captured at the Trinity River rotary screw traps, near Willow Creek (rkm 34), California, 2002.

Common Name	Scientific Name	Catch (n)
Klamath smallscale sucker	<i>Catostomus rimiculus</i>	8,388
American shad	<i>Alosa sapidissima</i>	1,368
Pacific lamprey	<i>Entosphenus tridentatus</i>	413
Speckled dace	<i>Rhinichthys osculus</i>	386
Sculpin species	<i>Cottus spp.</i>	101
Threespine stickleback	<i>Gasterosteus aculeatus</i>	70
Green sturgeon	<i>Acipenser medirostris</i>	22
Brown trout	<i>Salmo trutta</i>	4
Golden shiner	<i>Notemigonus crysoleucas</i>	3
Green sunfish	<i>Lepomis cyanellus</i>	3
Season Total		10,758

2003

A total of 8,877 non-target fishes were captured during 2003 (Table 11). Klamath smallscale sucker was the most numerous non-target species followed by Pacific lamprey, American shad, and green sturgeon (*Acipenser medirostris*).

Table 11. Catch totals of non-target fish species captured at the Trinity River rotary screw traps, near Willow Creek (rkm 34), California, 2003.

Common Name	Scientific Name	Catch (n)
Klamath smallscale sucker	<i>Catostomus rimiculus</i>	6,628
Pacific lamprey	<i>Entosphenus tridentatus</i>	1,218
American shad	<i>Alosa sapidissima</i>	412
Green sturgeon	<i>Acipenser medirostris</i>	318
Speckled dace	<i>Rhinichthys osculus</i>	187
Sculpin species	<i>Cottus spp.</i>	62
Threespine stickleback	<i>Gasterosteus aculeatus</i>	26
Sockeye salmon	<i>Oncorhynchus nerka</i>	9
Brown trout	<i>Salmo trutta</i>	7
Golden shiner	<i>Notemigonus crysoleucas</i>	5
Green sunfish	<i>Lepomis cyanellus</i>	3
Bullhead specie	<i>Ameirus sp.</i>	2
Season Total		8,877

2004

A total of 5,134 non-target fishes were captured in 2004, predominately Klamath smallscale suckers (Table 12). Other abundant species included American shad, Pacific lamprey, and speckled dace.

Table 12. Catch totals of non-target fish species captured at the Trinity River rotary screw traps, near Willow Creek (rkm 34), California, 2004.

Common Name	Scientific Name	Catch (n)
Klamath smallscale sucker	<i>Catostomus rimiculus</i>	2,935
American shad	<i>Alosa sapidissima</i>	778
Pacific lamprey	<i>Entosphenus tridentatus</i>	771
Speckled dace	<i>Rhinichthys osculus</i>	432
Sculpin species	<i>Cottus spp.</i>	132
Green sturgeon	<i>Acipenser medirostris</i>	38
Brown trout	<i>Salmo trutta</i>	21
Threespine stickleback	<i>Gasterosteus aculeatus</i>	19
Sockeye salmon	<i>Oncorhynchus nerka</i>	6
Bullhead specie	<i>Ameirus sp.</i>	2
Season Total		5,134

2005

A total of 12,561 non-target fishes were captured in 2005 (Table 13). Klamath smallscale sucker was the most numerous non-target species (Table 13). Other abundant species included Pacific lamprey, speckled dace, and green sturgeon.

Table 13. Catch totals of non-target fish species captured at the Trinity River rotary screw traps, near Willow Creek (rkm 34), California, 2005.

Common Name	Scientific Name	Catch (n)
Klamath smallscale sucker	<i>Catostomus rimiculus</i>	9,089
Pacific lamprey	<i>Entosphenus tridentatus</i>	2,575
Speckled dace	<i>Rhinichthys osculus</i>	491
Green sturgeon	<i>Acipenser medirostris</i>	253
Sculpin species	<i>Cottus spp.</i>	43
Threespine stickleback	<i>Gasterosteus aculeatus</i>	30
Green sunfish	<i>Lepomis cyanellus</i>	24
Golden shiner	<i>Notemigonus crysoleucas</i>	21
American shad	<i>Alosa sapidissima</i>	17
Brown trout	<i>Salmo trutta</i>	16
Sockeye salmon	<i>Oncorhynchus nerka</i>	1
Bullhead specie	<i>Ameirus sp.</i>	1
Season Total		12,561

Migration Rates

Due to the volitional release of hatchery reared salmonids (Chinook salmon, coho salmon, and steelhead), mean migration rates could not be calculated. However, maximum migration rates are presented based on the first capture of hatchery released salmon at the Willow Creek trap site.

Chinook salmon

Migration rates calculated from the initial release date and first ad-clip Chinook salmon captured ranged from 12 rkm/d in 2003 to 36 rkm/d in 2001 (Table 14).

Coho salmon

Migration rates calculated from the initial release date and first max-clip coho salmon captured ranged from 4 rkm/d in 2001 to 36 rkm/d in 2002 and 2004 (Table 15), although these values may not be valid due to the traps being installed after the hatchery release.

Table 14. Chinook salmon migration rates, as recorded at the Trinity River rotary screw traps near Willow Creek (rkm 34), California, 2001-2005.

Year	Season	Date First Released	Date First Captured	# of Days	Migration Rate (rkm/d)
2001	Spring	6/6/2001	6/10/2001	4	36
	Fall	10/1/2001	10/5/2001	4	36
2002	Spring	6/3/2002	6/8/2002	5	29
	Fall	10/10/2002	10/18/2002	8	18
2003	Spring	6/3/2003	6/15/2003	12	12
	Fall	10/1/2003	10/6/2003	5	29
2004	Spring	6/4/2004	6/14/2004	10	14
	Fall	10/1/2004	10/6/2004	5	29
2005	Spring	6/1/2005	6/10/2005	9	16

Table 15. Coho salmon migration rates, as recorded at the Trinity River rotary screw traps near Willow Creek (rkm 34), California, 2001-2005.

Year	Season	Date First Released	Date First Captured	# of Days	Migration Rate (rkm/d)
2001	Spring	3/15/2001	4/20/2001*	36	4 *
2002	Spring	3/15/2002	3/19/2002	4	36
2003	Spring	3/17/2003	4/3/2003	17	9
2004	Spring	3/15/2004	3/19/2004*	4	36 *
2005	Spring	3/15/2005	3/20/2005	5	29

*Values should be interpreted with caution because the hatchery release occurred prior to trap installation.

Steelhead

Migration rates calculated from the initial release date and first ad-clip steelhead captured ranged from 6 rkm/d in 2001 to 29 rkm/d in 2002 (Table 16), although these values may not be valid due to the traps being installed after the hatchery release in 2001.

Table 16. Steelhead migration rates, as recorded at the Trinity River rotary screw traps near Willow Creek (rkm 34), California, 2001-2005.

Year	Season	Date First Released	Date First Captured	# of Days	Migration Rate (rkm/d)
2001	Spring	3/15/2001	4/10/2001*	26	6 *
2002	Spring	3/15/2002	3/20/2002	5	29
2003	Spring	3/17/2003	4/2/2003	16	9
2004	Spring	3/15/2004	3/24/2004*	9	16 *
2005	Spring	3/15/2005	4/3/2005	19	8

*Values should be interpreted with caution because the hatchery release occurred prior to trap installation.

Abundance Indices

Abundance indices are greatly influenced by river discharge and one must use caution in comparing indices within or between years for absolute numbers of fish passing a site. However, abundance indices are generally thought to be adequate indicators of emigration timing and duration if sampling occurred in all weeks of the sampling period.

Chinook salmon

Total yearly Chinook salmon abundance indices ranged from 283,604 in 2004 to 1,801,346 in 2005 (Table 17; Appendices 1-5).

Table 17. Yearly Chinook salmon Abundance Indices, Willow Creek Trap Site, 2001-2005.

Year	Natural Age-0	Natural Age-1	Hatchery Age-0	Total
2001	714,126	38	173,828	887,992
2002	539,815	322	213,260	753,397
2003	276,799	1,281	86,288	364,367
2004	196,625	881	86,098	283,604
2005	1,489,124	645	311,577	1,801,346

2001

Spring monitoring in 2001 began in April (JW 15), with few natural age-0 Chinook salmon captured before mid-May (JW 20; Figure 3). Abundance indices increased weekly through June, the peak weekly Chinook salmon natural age-0 abundance index occurred JW 24 (Appendix 1). The peak weekly abundance index for hatchery age-0 Chinook salmon occurred during JW 25. The peak weekly hatchery age-0 Chinook salmon abundance index during fall monitoring occurred JW 41. Based on the abundance indices, the hatchery component of Chinook salmon outmigration was 19.1% for the spring sampling period and 85.1% for the fall sampling period.

2002

Spring monitoring in 2002 began in March (JW 11), with few natural age-0 Chinook salmon captured before mid-April (JW 16; Figure 3). Abundance indices increased weekly through May, an initial peak weekly Chinook salmon natural age-0 abundance index occurred JW 20 (Appendix 2) with a second peak JW 24. The peak weekly abundance index for hatchery age-0 Chinook salmon was during JW 25. During fall monitoring, the peak weekly hatchery age-0 Chinook salmon abundance index occurred JW 42. Based on the abundance indices, the hatchery component of Chinook salmon outmigration was 23.5% for the spring sampling period and 77.0% for the fall sampling period.

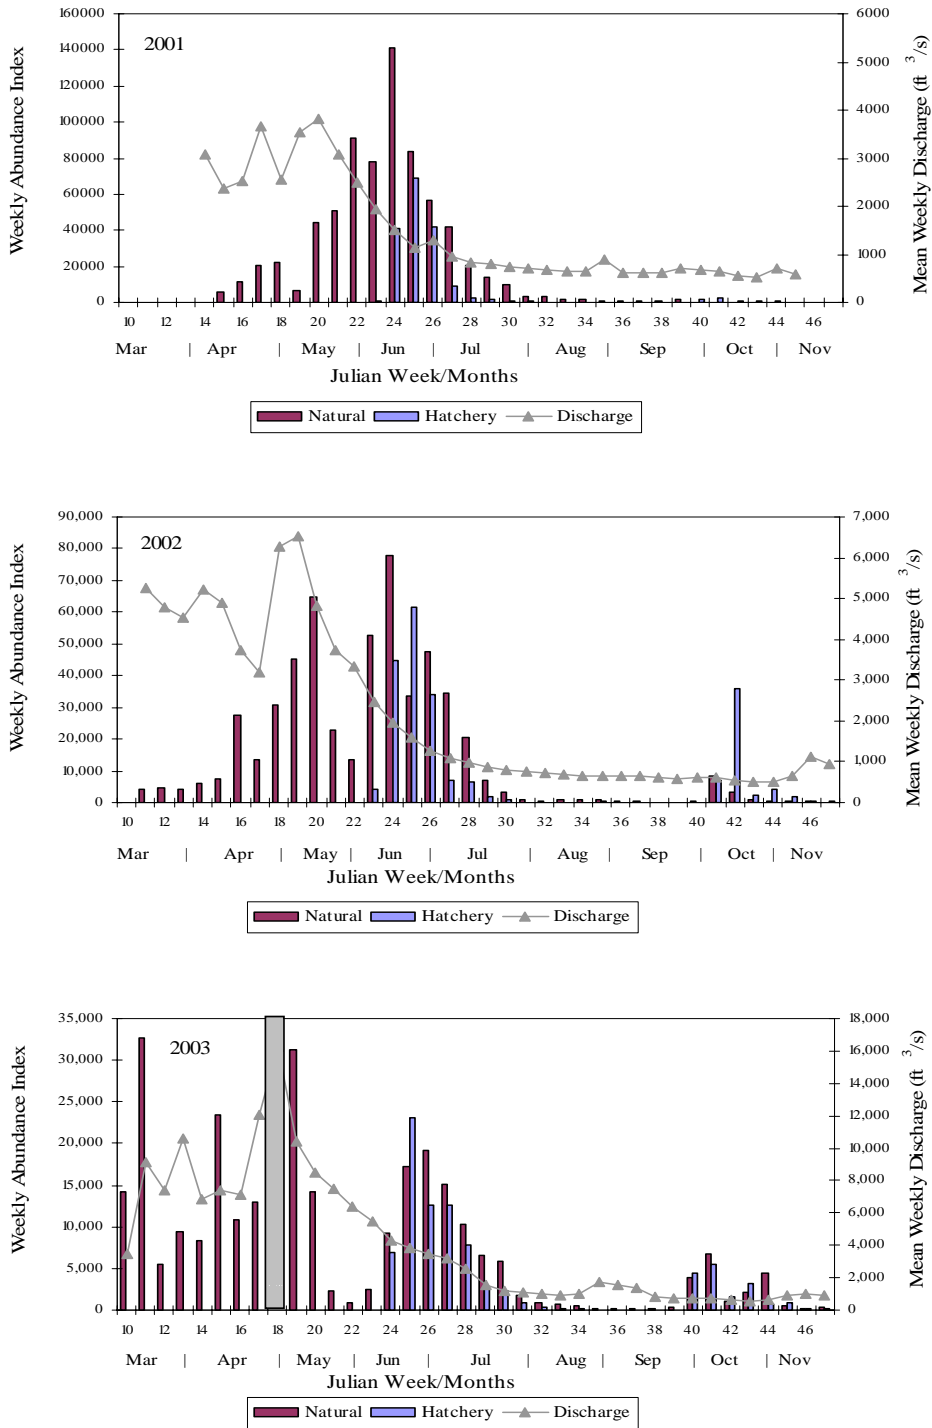

Figure 3. Weekly abundance indices for natural age-0 and hatchery age-0 Chinook salmon captured at the Trinity River rotary screw traps near Willow Creek (rkm 34), California, and mean daily discharge (ft³/s) as recorded at Hoopa, California (US Geological Survey Water Resource gauge station #11-530000), 2001-2005. Shaded blocks represent Julian Weeks when traps were not in operation.

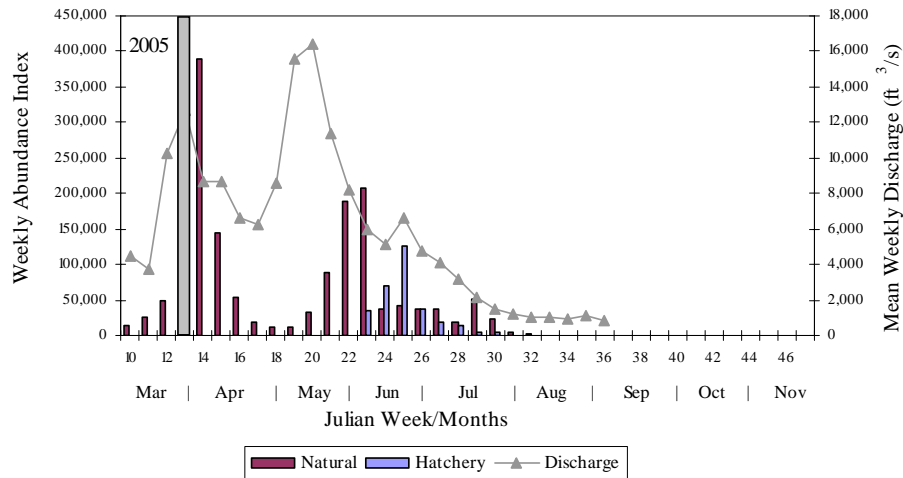

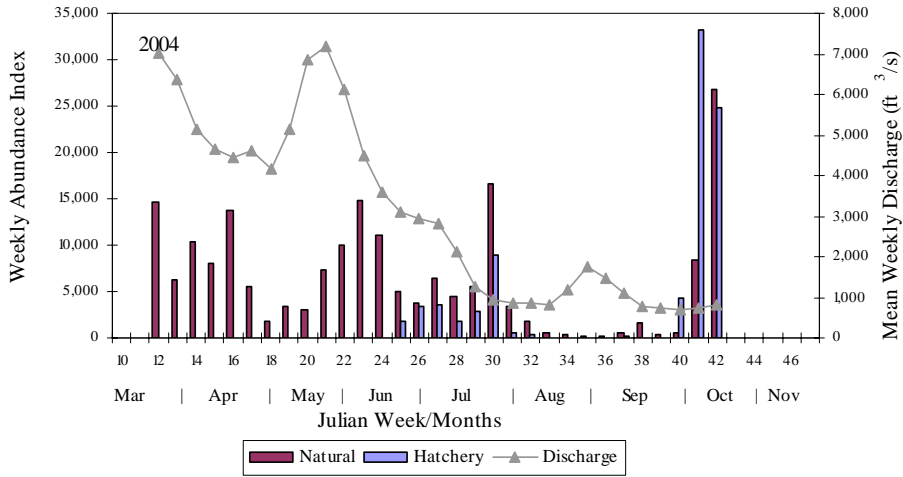

Figure 3 (continued). Weekly abundance indices for natural age-0 and hatchery age-0 Chinook salmon captured at the Trinity River rotary screw traps near Willow Creek (rkm 34), California, and mean daily discharge (ft^3/s) as recorded at Hoopa, California (US Geological Survey Water Resource gauge station #11-530000), 2001-2005. Shaded blocks represent Julian Weeks when traps were not in operation.

2003

Spring monitoring in 2003 began in March (JW 10), with many natural age-0 Chinook salmon captured through May (JW 20; Figure 3). An initial peak weekly Chinook salmon natural age-0 abundance index occurred JW 11 (Appendix 3), with a second peak JW 19, and a third peak JW 26. Sampling did not occur JW 18 so it is uncertain whether the peak in JW 19 is the actual peak in the early sampling period. The peak weekly abundance index for hatchery age-0 Chinook salmon during spring monitoring occurred during JW 25. During fall monitoring, the peak weekly Chinook salmon hatchery age-0 abundance index occurred JW 41. Based on the abundance indices, the hatchery

component of Chinook salmon outmigration was 21.3% for the spring sampling period and 46.0% for the fall sampling period.

2004

Spring monitoring in 2004 began in March (JW 12), with many natural age-0 Chinook salmon captured through April (JW 17; Figure 3). Although no clear dominant peak in the Chinook salmon natural age-0 abundance index occurred, peaks did occur on JW 12, JW 16, JW 23 and JW 30 (Appendix 4). The peak weekly abundance index for hatchery age-0 Chinook salmon during spring monitoring occurred during JW 30. During fall monitoring, the peak weekly Chinook salmon hatchery age-0 abundance index occurred JW 41. Based on the abundance indices, the hatchery component of Chinook salmon outmigration was 12.8% for the spring sampling period and 63.6% for the fall sampling period.

2005

Spring monitoring in 2005 began in March (JW 10), with many natural age-0 Chinook salmon captured through April (JW 17; Figure 3). Sampling did not occur JW 13 so it is uncertain whether the peak in JW 14 is the actual peak in the early sampling period. A second peak in the Chinook salmon natural age-0 abundance index occurred JW 23 (Appendix 5). The peak weekly abundance index for hatchery age-0 Chinook salmon during spring monitoring occurred during JW 25. Based on the abundance indices, the hatchery component of Chinook salmon outmigration was 17.3% for the spring sampling period. No fall monitoring occurred in 2005.

Coho salmon

Total yearly coho salmon abundance indices ranged from 32,815 in 2004 to 194,846 in 2005 (Table 18; Appendices 6-10).

Table 18. Yearly coho salmon Abundance Indices, Willow Creek Trap Site, 2001-2005.

Year	Natural Age-0	Natural Age-1	Hatchery Age-1	Total
2001	6,043	3,542	23,562	33,147
2002	34,600	19,192	27,238	81,030
2003	65,782	8,949	14,967	89,698
2004	5,692	3,102	24,021	32,815
2005	154,618	4,394	35,834	194,846

2001

Spring monitoring in 2001 began in April (JW 15), with few coho salmon captured before mid-May (JW 19; Figure 4). The peak weekly coho salmon natural and hatchery age-1 abundance indices occurred JW 20 (Appendix 6). The peak weekly coho salmon natural age-0 abundance index occurred JW 22. Based on the abundance indices, hatchery produced fish made up 86.9% of the spring period age-1 coho salmon outmigration. No coho salmon were captured during the fall monitoring period.

2002

Spring monitoring in 2002 began in March (JW 11), with many natural age-0 coho salmon captured before April (JW 14; Figure 4). The peak weekly coho salmon natural and hatchery age-1 abundance indices occurred JW 18 (Appendix 7). The peak weekly coho salmon natural age-0 abundance index occurred JW 18. Based on the abundance indices, hatchery produced fish made up 58.7% of the spring period age-1 coho salmon outmigration. Coho salmon abundance indices during the fall monitoring period were very small compared to the spring monitoring period.

2003

Spring monitoring in 2003 began in March (JW 10), with many natural age-0 coho salmon captured before May (JW 18; Figure 4). The peak weekly coho salmon natural and hatchery age-1 abundance indices occurred JW 19 (Appendix 8). Sampling did not occur JW 18 so it is uncertain whether the peak in JW 19 is the actual peak in the early sampling period. The peak weekly coho salmon natural age-0 abundance index occurred JW 13. Based on the abundance indices, hatchery produced fish made up 62.6% of the spring period age-1 coho salmon outmigration. No coho salmon were captured during the fall monitoring period.

2004

Spring monitoring in 2004 began in March (JW 12), with many coho salmon captured before May (JW 18; Figure 4). The peak weekly coho salmon natural and hatchery age-1 abundance indices occurred JW 12, the first week of sampling (Appendix 9). The peak weekly natural age-0 coho salmon abundance index also occurred JW 12. Based on the abundance indices, hatchery produced fish made up 88.6% of the spring period age-1 coho salmon outmigration. No coho salmon were captured during the fall monitoring period.

2005

Spring monitoring in 2005 began in March (JW 10), with many coho salmon captured before May (JW 18; Figure 4). The peak weekly coho salmon natural and hatchery age-1 abundance indices occurred JW 19 (Appendix 10). The peak weekly coho salmon natural age-0 abundance index occurred JW 14, although because sampling did not occur JW 13, it is impossible to tell if a peak occurred in JW 13. Based on the abundance indices, hatchery produced fish made up 89.1% of the spring period age-1 coho salmon outmigration. No fall monitoring occurred in 2005.

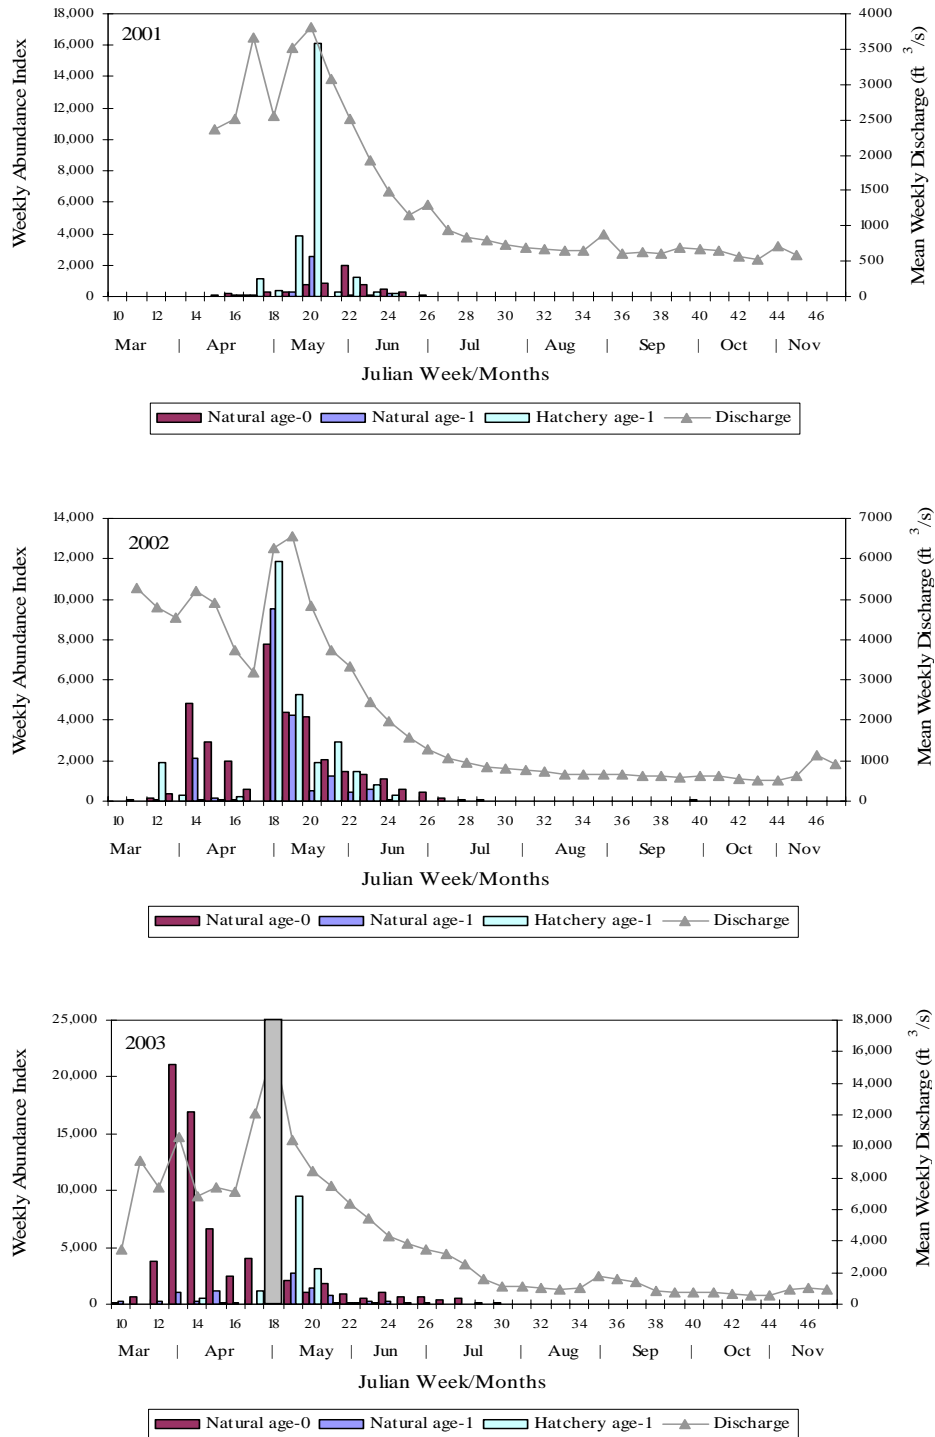

Figure 4. Weekly abundance indices for natural age-0, natural age-1, and hatchery age-1 coho salmon captured at the Trinity River rotary screw traps near Willow Creek (rkm 34), California, and mean daily discharge (ft^3/s) as recorded at Hoopa, California (US Geological Survey Water Resource gauge station #11-530000), 2001-2005. Shaded blocks represent Julian Weeks when traps were not in operation.

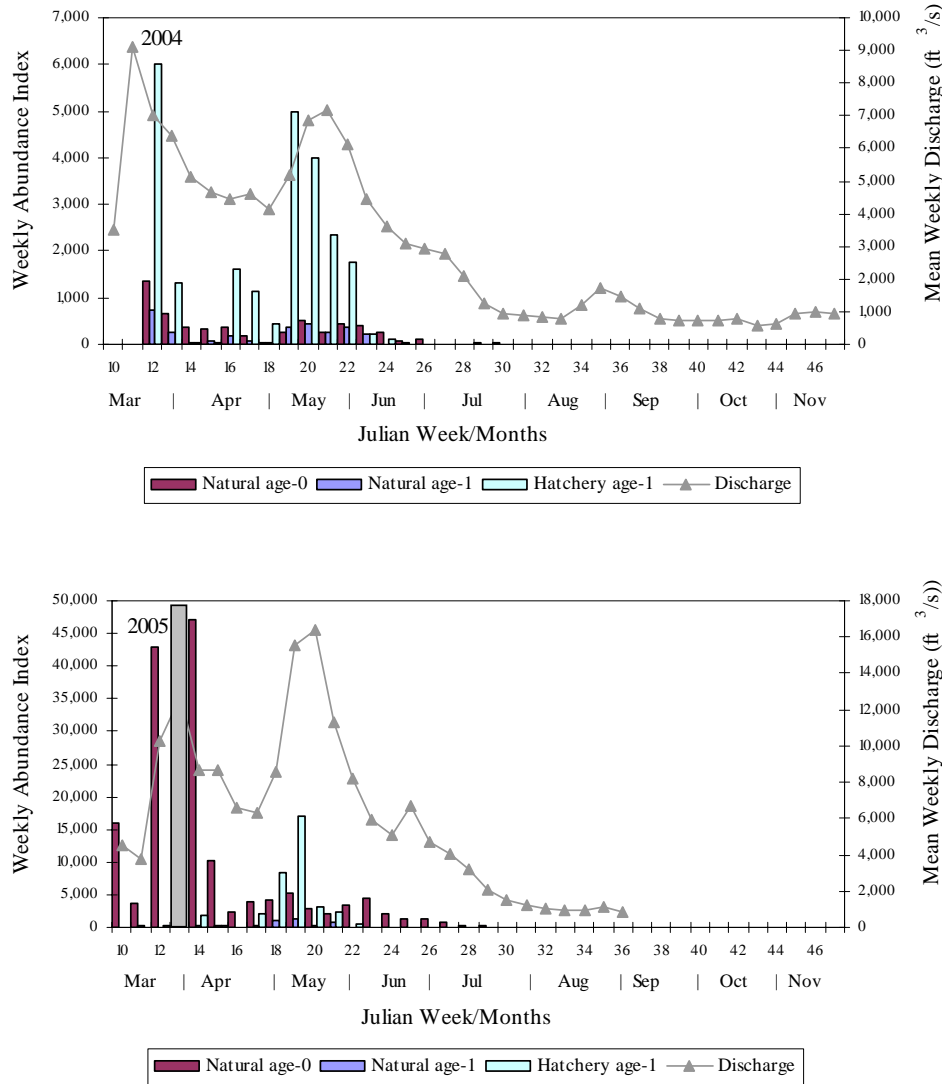

Figure 4 (continued). Weekly abundance indices for natural age-0, natural age-1, and hatchery age-1 coho salmon captured at the Trinity River rotary screw traps near Willow Creek (rkm 34), California, and mean daily discharge (ft³/s) as recorded at Hoopa, California (US Geological Survey Water Resource gauge station #11-530000), 2001-2005. Shaded blocks represent Julian Weeks when traps were not in operation.

Steelhead

Total yearly steelhead abundance indices ranged from 60,803 in 2004 to 82,945 in 2003 (Table 19; Appendices 11-15).

Table 19. Yearly steelhead Abundance Indices, Willow Creek Trap Site, 2001-2005.

Year	Natural Age-0	Natural Age-1	Natural Age-2	Hatchery Age-1	Total
2001	4,391	21,823	23,500	25,656	75,370
2002	28,658	12,102	3,563	18,565	62,888
2003	40,146	17,064	3,624	22,111	82,945
2004	6,707	28,693	14,366	11,037	60,803
2005	26,799	29,960	5,480	11,684	73,923

2001

Spring monitoring in 2001 began in April (JW 15), with most steelhead captured before July (JW 27; Figure 5). The peak weekly steelhead natural and hatchery age-1 abundance indices occurred JW 16 (Appendix 11). Due to the large catch of hatchery steelhead during the first week of sampling, the peak of emigration may have already occurred when trapping was initiated. The peak weekly steelhead natural age-0 abundance index occurred JW 25. Based on the abundance indices, hatchery produced fish made up 36.3% of the spring period age-1 and older steelhead outmigration. Natural steelhead abundance indices during the fall monitoring period were low compared to those for the spring monitoring period and no hatchery produced steelhead were captured during this period.

2002

Spring monitoring in 2002 began in March (JW 11), with most steelhead captured before July (JW 27; Figure 5). The peak weekly steelhead natural age-1 index occurred JW 19 and peak weekly hatchery age-1 abundance index occurred JW 18 (Appendix 12). The peak weekly steelhead natural age-0 abundance index occurred JW 24. Based on the abundance indices, hatchery produced fish made up 54.5% of the spring period age-1 and older steelhead emigration. Natural steelhead abundance indices during the fall monitoring period were low compared to those for the spring monitoring period and no hatchery produced steelhead were captured during this period.

2003

Spring monitoring in 2003 began in March (JW 10), with most steelhead captured before August (JW 32; Figure 5). The peak weekly steelhead natural age-1 index occurred JW 20 and peak weekly hatchery age-1 abundance index occurred JW 17 (Appendix 13). Sampling did not occur JW 18 so it is uncertain whether the hatchery and natural age-1 steelhead peaks during JW 17 and JW 20, respectively, are the actual peaks of the emigration. The peak weekly steelhead natural age-0 abundance index occurred JW 28. Based on the abundance indices, hatchery produced fish made up 51.8% of the spring period age-1 and older steelhead outmigration. Steelhead abundance indices during the fall monitoring period were low compared to those for the spring monitoring period.

Figure 5. Weekly abundance indices for natural age-0, natural age-1, and hatchery age-1 steelhead captured at the Trinity River rotary screw traps near Willow Creek (rkm 34), California, and mean daily discharge (ft³/s) as recorded at Hoopa, California (US Geological Survey Water Resource gauge station #11-530000), 2001-2005. Shaded blocks represent Julian Weeks when traps were not in operation.

Figure 5 (continued). Weekly abundance indices for natural age-0 natural age-1 and hatchery age-1 steelhead captured at the Trinity River rotary screw traps near Willow Creek (rkm 34), California, and mean daily discharge (ft³/s) as recorded at Hoopa, California (US Geological Survey Water Resource gauge station #11-530000), 2001-2005. Shaded blocks represent Julian Weeks when traps were not in operation.

2004

Spring monitoring in 2004 began in March (JW 12), with most steelhead captured before July (JW 27; Figure 5). The peak weekly steelhead natural and hatchery age-1 abundance indices occurred JW 13 (Appendix 14). The peak weekly steelhead natural age-0 abundance index occurred JW 23. Based on the abundance indices, hatchery produced fish made up 20.4% of the spring period age-1 and older steelhead emigration. Natural steelhead abundance indices during the fall monitoring period were very low

compared to those for the spring monitoring period and no hatchery produced steelhead were captured during this period.

2005

Spring monitoring in 2005 began in March (JW 10), with most steelhead captured before August (JW 32; Figure 5). The peak weekly steelhead natural age-1 index occurred JW 14 and peak weekly hatchery age-1 abundance index occurred JW 19 (Appendix 15). Sampling did not occur JW 13 so it is uncertain whether the natural age-1 steelhead peak was the actual peaks of the emigration. The peak weekly steelhead natural age-0 abundance index occurred JW 20. Based on the abundance indices, hatchery produced fish made up 24.8% of the spring period age-1 and older steelhead emigration. No fall monitoring occurred in 2005.

Emigration Timing

Chinook salmon

The emigration period of natural Chinook salmon from the Trinity River appears to have two relatively distinct emigration periods, a late-winter peak and a spring peak. In some years the late-winter peak may have occurred prior to trap installation, and other years the peak occurred during the early trapping period (Figure 3, Appendices 1-5). In all years Chinook salmon were caught the first day trapping occurred, suggesting that juvenile Chinook salmon were present before traps were installed. By late August, the abundance indices for all years was very low. The Chinook emigration during the fall monitoring period generally occurred over a five week period shortly after the fall hatchery release.

Peaks in emigration generally occurred earlier for natural age-0 Chinook salmon (Table 20) compared to hatchery age-0 Chinook salmon, while emigration duration, the period when fish are captured, was longer for natural compared to hatchery Chinook salmon.

Table 20. Spring season Chinook salmon emigration timing and duration, Willow Creek Trap Site, 2001-2005. Values represent Julian Weeks.

Year	Emigration Duration		Emigration Peak	
	Age-0	Hatchery	Age-0	Hatchery
2001	15-39	23-36	24	25
2002	11-39	23-39	24	25
2003	10-39	23-39	N/A*	25
2004	12-39	24-39	12,23,30**	30
2005	10-36	23-36	N/A*	25

*Due to missing sampling weeks, these values could not be determined.

**Multiple peaks in sampling season

Coho salmon

The emigration period of natural age-0 coho salmon from the Trinity River was protracted over the period from March through July. (Figure 4, Appendices 6-10). In most years age-0 coho salmon were caught the first day trapping occurred, suggesting that age-0 coho salmon were present before traps were installed. Peaks in emigration generally occurred between Julian Weeks 12 and 22 for natural age-0 coho salmon (Table 21).

Table 21. Spring season coho salmon age-0 emigration timing and duration, Willow Creek Trap Site, 2001-2005. Values represent Julian Weeks.

Year	Emigration Duration	Emigration Peak
	Age-0	Age-0
2001	16-26	22
2002	11-35	18
2003	10-37	N/A*
2004	12-37	12
2005	10-30	N/A*

*Due to missing sampling weeks, these values could not be determined.

The emigration period of natural age-1 coho salmon from the Trinity River appears to have one distinct emigration period which typically ends in early to mid-June (Figure 4, Appendices 6-10). In most years age-1 coho salmon were caught the first week trapping occurred, suggesting that age-1 coho salmon were present before traps were installed. Peaks in emigration were generally similar for natural age-1 coho salmon and hatchery age-1 coho salmon (Table 22). Emigration duration was longer for natural compared to hatchery age-1 coho salmon.

Table 22. Spring season natural and hatchery coho salmon age-1 emigration timing and duration, Willow Creek Trap Site, 2001-2005. Values represent Julian Weeks.

Year	Emigration Duration		Emigration Peak	
	Natural	Hatchery	Natural	Hatchery
2001	15-29	16-24	20	20
2002	12-29	12-24	18	18
2003	10-36	14-28	N/A*	N/A*
2004	12-25	12-24	12	12,19**
2005	10-27	12-24	N/A*	N/A*

*Due to missing sampling weeks, these values could not be determined.

**Multiple peaks in sampling season

Steelhead

The emigration period of natural age-0 steelhead from the Trinity River typically begins in April and occurs throughout the monitoring season with most movement occurring from April through July (Figure 5, Appendices 11-15). In most years, age-0 steelhead were not caught until well into the sampling period, suggesting that the majority of the age-0 steelhead emigration was captured during the sampling periods. Peaks in emigration generally occurred between Julian Weeks 23 and 25 for natural age-0 steelhead (Table 23).

Table 23. Spring season steelhead age-0 emigration timing and duration, Willow Creek Trap Site, 2001-2005. Values represent Julian Weeks.

Year	Emigration Duration	Emigration Peak
	Age-0	Age-0
2001	16-39	25
2002	12-39	24
2003	13-39	N/A*
2004	12-38	23
2005	10-36	N/A*

*Due to missing sampling weeks, these values could not be determined.

The majority of the natural age-1+ (includes ages 1, 2, and 3) steelhead emigration from the Trinity River extends at least from March through June, (Figure 5, Appendices 11-15). In most years age-1+ steelhead were caught the first week trapping occurred, suggesting that age-1+ steelhead were present before traps were installed. The emigration for age-1 hatchery steelhead is similar except that it typically tapers off by the end of May. Peaks in emigration were generally similar for natural age-1+ steelhead and hatchery age-1 steelhead (Table 24).

Table 24. Spring season natural (includes ages 1, 2, and 3) and hatchery steelhead emigration timing and duration, Willow Creek Trap Site, 2001-2005. Values represent Julian Weeks.

Year	Emigration Duration		Emigration Peak	
	Natural	Hatchery	Natural	Hatchery

*Due to missing sampling weeks, these values could not be determined.

Population Estimates

Beginning in 2002, an intensive mark recapture program was conducted at the Willow Creek trap site. Only age-0 Chinook salmon were captured in quantities sufficient for conducting mark-recapture. Population estimates include both natural and hatchery age-0 Chinook salmon because hatchery Chinook salmon were not 100% marked. Season wide marking rate ranged from 11.5% in 2002 to 62.5% in 2005 (Table 25). For the periods that mark-recapture based population estimates were conducted, the 95% confidence interval ranged from +/-8.9% of the population estimate in 2005 to +/-54.9% of the population estimate in 2003 (Table 26). At this time, estimators for population estimates and associated variances for periods when mark-recapture estimates were not conducted have not been developed for the Willow Creek trap site data. It is anticipated that this will be one of the issues/tasks reviewed during an outmigration monitoring review. Annual age-0 Chinook salmon mark-recapture population estimates and abundance indices for the same time periods were significantly correlated ($r=0.982$, $n=4$, $p<0.005$) suggesting that the abundance indices may be a valid measure of relative population size (Figure 6). Direct comparisons of population estimates between years (Table 26, Appendices 16-19, Figure 6) should not be done with these data because the marking period varied from year-to-year (Table 25). Fall sampling did not occur in each year, and mark recapture estimates were not calculated for fall sampling periods.

Table 25. Age-0 Chinook salmon mark-recapture period, marking rate, and recapture rate, Willow Creek Trap Site, 2001-2005.

Year	Marking Period	Catch	# Marked	Marking Rate	# Recaps	Recapture Rate
2002	JW 17-27	55,146	6,362	11.5%	212	3.3%
2003	JW 24-30	10,283	2,208	21.4%	30	1.4%
2004	JW 13-19, JW 21-30	10,216	3,032	29.7%	31	1.0%
2005	JW 14-19, JW 21-27	49,468	30,897	62.5%	636	2.1%

Table 26. Natural and hatchery age-0 Chinook salmon stratified population estimates for periods mark-recapture population estimates were conducted, Willow Creek Trap Site, 2002-2005.

Year	Estimate	Stratified Population Estimates	
		Lower 95% Confidence Level	Upper 95% Confidence Level
2002	1,330,070	1,076,791	1,583,349
2003	671,993	303,132	1,040,854
2004	430,687	302,839	558,536
2005	2,292,137	2,087,850	2,496,424

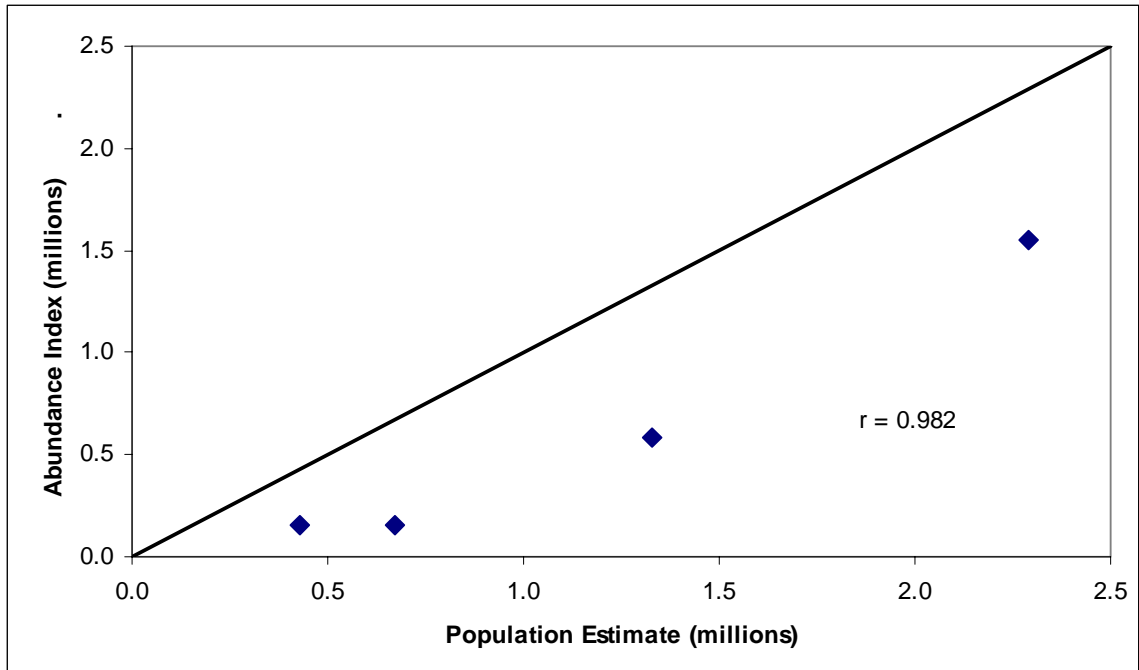

Figure 6. Relationship between mark-recapture population estimates and abundance indices for natural and hatchery age-0 Chinook salmon for periods mark-recapture population estimates were conducted at the Trinity River rotary screw traps near Willow Creek (rkm 34), California, 2002-2005. Solid line represents a one-to-one relationship.

Fork Lengths

Chinook salmon

2001

Mean FL of age-0 Chinook salmon generally increased over the 2001 sampling season (Figure 7; Appendix 20). Mean FL increased noticeably in Julian Week 40 with the arrival of fall released hatchery fish.

2002

Mean FL of age-0 Chinook salmon generally increased over the 2002 sampling season (Figure 7; Appendix 21).

2003

Mean FL of age-0 Chinook salmon generally increased over the 2003 sampling season (Figure 7; Appendix 22).

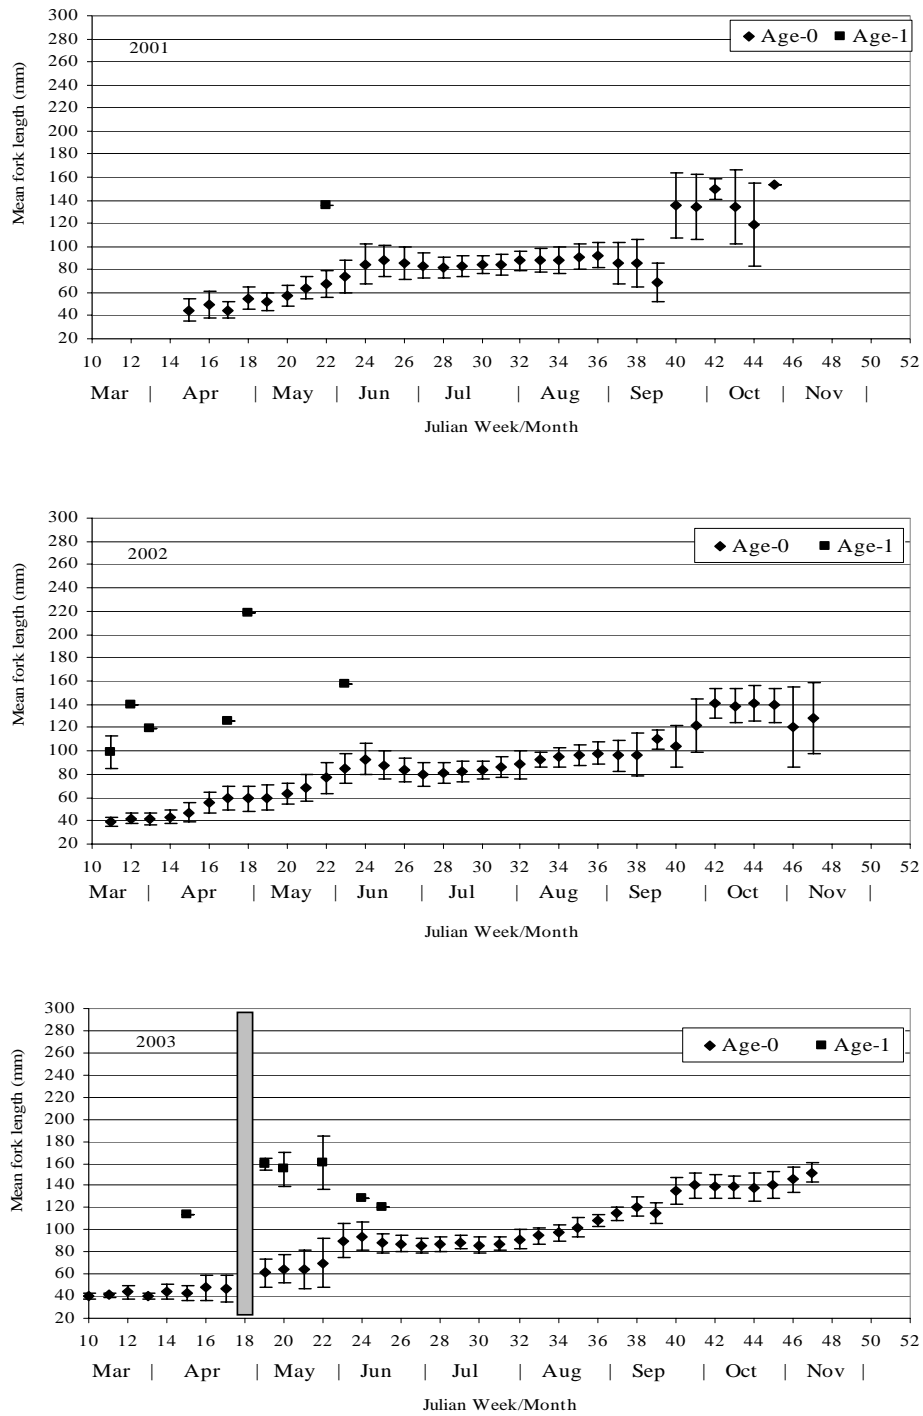

Figure 7. Weekly mean fork lengths for natural age-0 and age-1 Chinook salmon captured at the Trinity River rotary screw traps near Willow Creek (rkm 34), California. Shaded blocks represent Julian Weeks when traps were not in operation. Error bars represent one standard deviation of the mean.

Figure 7 (continued). Weekly mean fork lengths for natural age-0 and age-1 Chinook salmon captured at the Trinity River rotary screw traps near Willow Creek (rkm 34), California, 2001-2005. Shaded blocks represent Julian Weeks when traps were not in operation. Error bars represent one standard deviation of the mean.

2004

Mean FL of age-0 Chinook salmon generally increased over the 2004 sampling season (Figure 7; Appendix 23). Mean FL increased noticeably in Julian Week 40 with the arrival of fall released hatchery fish.

2005

Mean FL of age-0 Chinook salmon generally increased over the 2005 sampling season (Figure 7; Appendix 24).

Coho salmon

2001

Mean FL of age-0 coho salmon generally increased over the 2001 sampling season (Figure 8; Appendix 20). Mean FL of natural and hatchery age-1 coho salmon generally decreased over the 2001 sampling season.

2002

Mean FL of age-0 coho salmon generally increased over the 2002 sampling season (Figure 8; Appendix 21). Mean FL of natural and hatchery age-1 coho salmon generally decreased over the 2002 sampling season.

2003

Mean FL of age-0 and natural age-1 coho salmon generally increased over the 2003 sampling season (Figure 8; Appendix 22). Mean FL of hatchery age-1 coho salmon was relatively stable over the 2003 sampling season.

2004

Mean FL of age-0 coho salmon generally increased over the 2004 sampling season (Figure 8; Appendix 23). Mean FL of natural and hatchery age-1 coho salmon were relatively stable over the 2004 sampling season.

2005

Mean FL of age-0 and natural age-1 coho salmon generally increased over the 2005 sampling season (Figure 8; Appendix 24). Mean FL hatchery age-1 coho salmon was relatively stable over the 2005 sampling season.

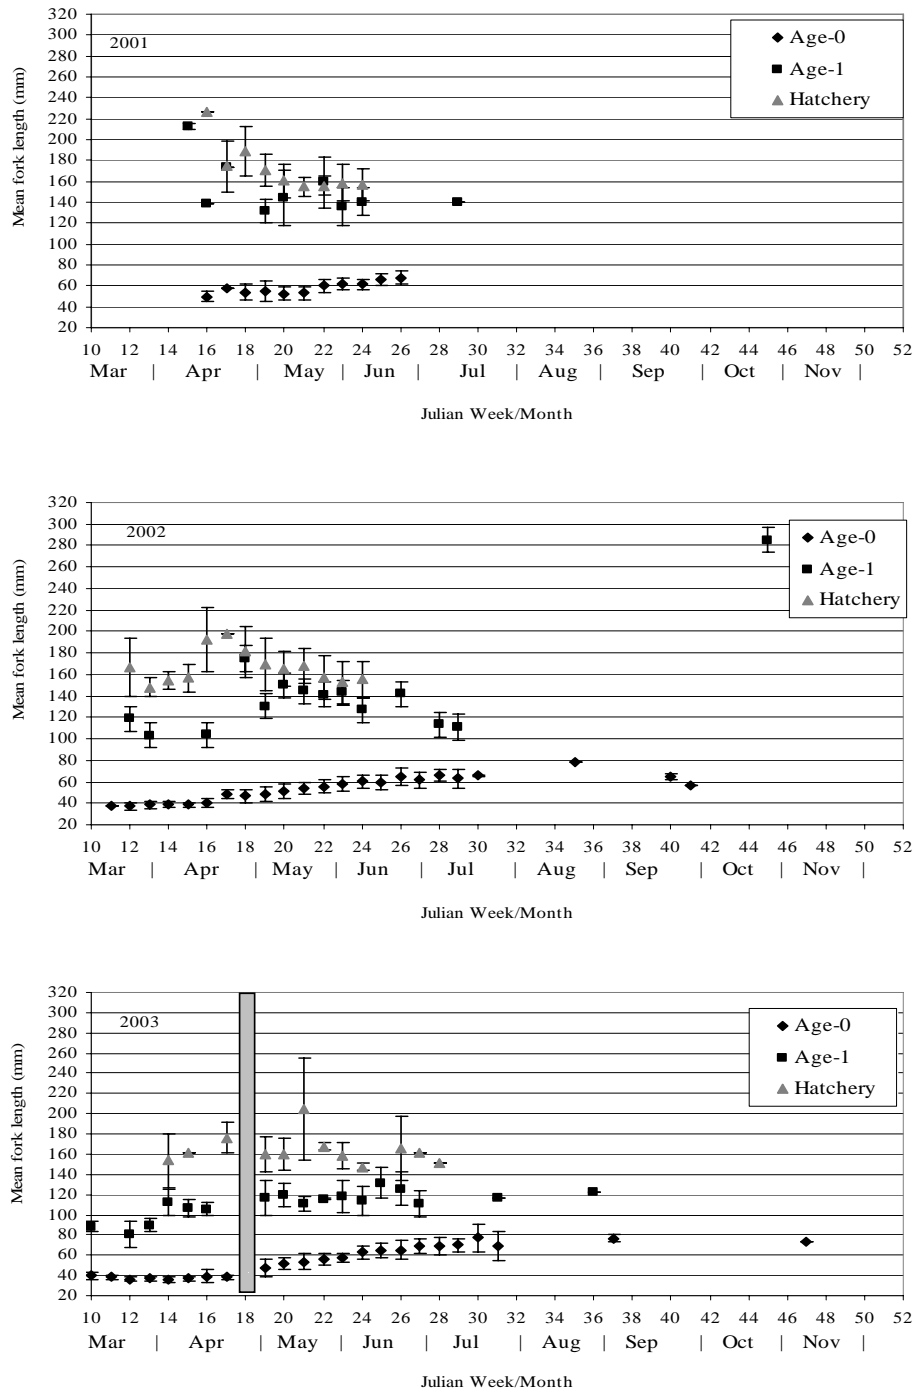

Figure 8. Weekly mean fork lengths for natural age-0, age-1 and hatchery coho salmon captured at the Trinity River rotary screw traps near Willow Creek (rkm 34), California, 2001-2005. Shaded blocks represent Julian Weeks when traps were not in operation. Error bars represent one standard deviation of the mean.

Figure 8 (continued). Weekly mean fork lengths for natural age-0, age-1 and hatchery coho salmon captured at the Trinity River rotary screw traps near Willow Creek (rkm 34), California, 2001-2005. Shaded blocks represent Julian Weeks when traps were not in operation. Error bars represent one standard deviation of the mean.

Steelhead

2001

Mean FL of age-0 steelhead generally increased over the 2001 sampling season (Figure 9; Appendix 25). Mean FL of natural age-1 steelhead increased then was relatively constant while natural age-2 steelhead mean FL generally decreased over the 2001 sampling season. Mean FL of hatchery age-1 steelhead was relatively constant.

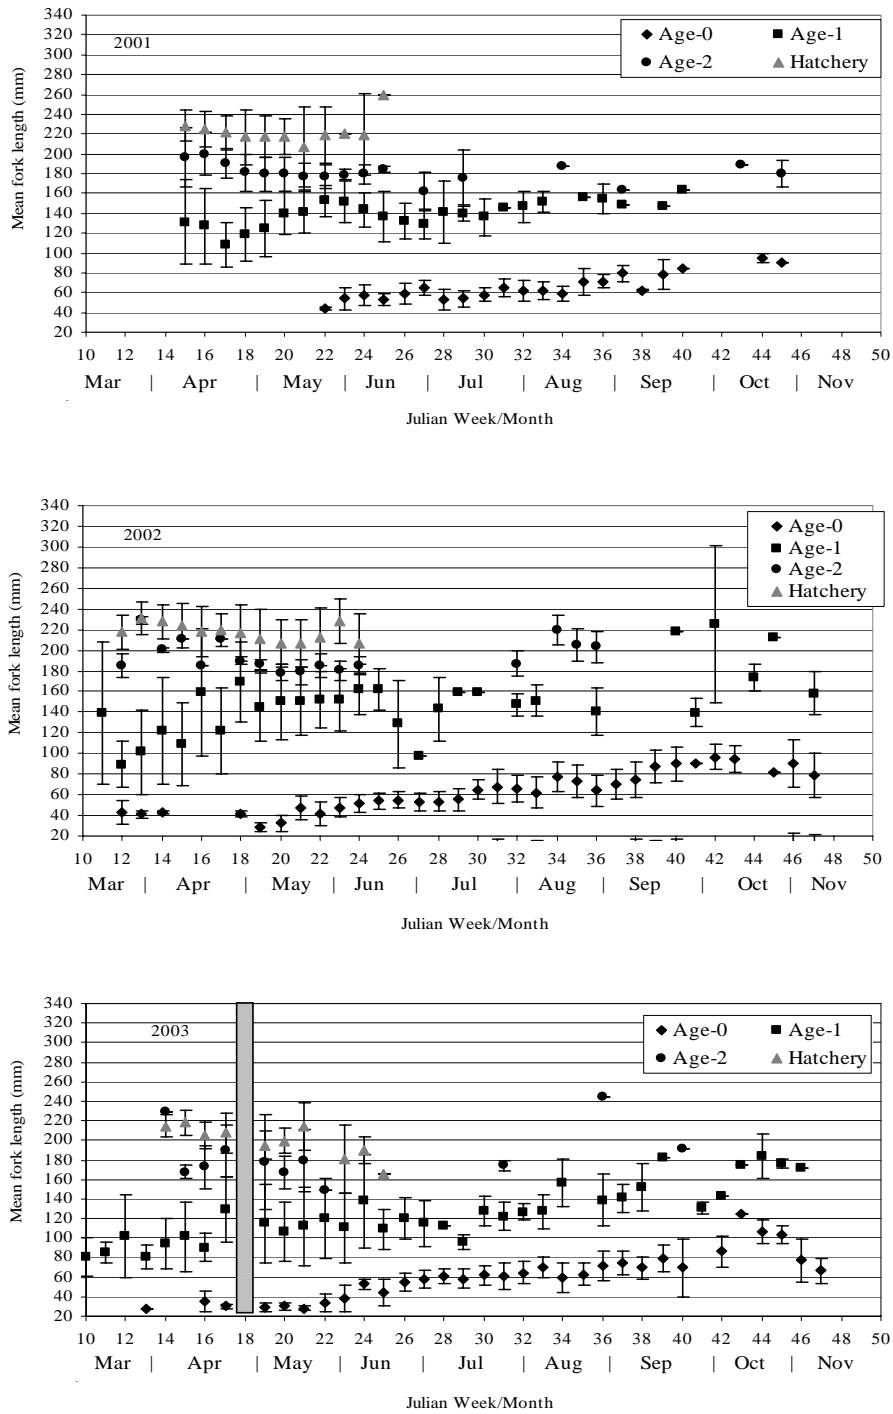

Figure 9. Weekly mean fork lengths for natural age-0, age-1, age-2, and hatchery steelhead captured at the Trinity River rotary screw traps near Willow Creek (rkm 34), California, 2001-2005. Shaded blocks represent Julian Weeks when traps were not in operation. Error bars represent one standard deviation of the mean.

Figure 9 (continued). Weekly mean fork lengths for natural age-0, age-1, age-2, and hatchery steelhead captured at the Trinity River rotary screw traps near Willow Creek (rkm 34), California, 2001-2005. Shaded blocks represent Julian Weeks when traps were not in operation. Error bars represent one standard deviation of the mean.

2002

Mean FL of age-0 and natural age-1 steelhead generally increased over the 2002 sampling season (Figure 9; Appendix 26). Mean FL of hatchery age-1 and natural age-2 steelhead generally decreased over the 2002 sampling season.

2003

Mean FL of age-0 and natural age-1 steelhead generally increased over the 2003 sampling season while mean FL of hatchery age-1 steelhead generally decreased (Figure 9; Appendix 27). Mean FL of age-2 steelhead was highly variable with no obvious trend.

2004

Mean FL of age-0 and natural age-1 steelhead generally increased over the 2004 sampling season (Figure 9; Appendix 28). Mean FL of hatchery age-1 steelhead generally decreased while natural age-2 steelhead mean FL was relative constant over the 2004 sampling season.

2005

Mean FL of age-0 steelhead generally increased over the 2005 sampling season (Figure 9; Appendix 29). Mean FL of natural age-1 and age-2 steelhead generally increased through mid-May the gradually decreased. Not trend was observed in the mean FL of hatchery age-1 during the 2005 sampling season.

Summary/Discussion

Juvenile salmonid emigration from the mainstem Trinity River has been monitored at the Willow Creek site since 1989 with rotary screw traps. This data series report summarizes the outmigrant monitoring data collected from 2001 through 2005 cooperatively by the Arcata Fish and Wildlife Office and Yurok Tribal Fisheries Program. It is intended that this information will provide basic biological information that can be used by managers to evaluate the effectiveness of habitat restoration efforts, especially the new flow regimes recommended in the Record of Decision, in restoring the fishery resources of the Trinity River. In addition to providing summarized information, topic specific information collected by this project and combined with data from other projects will be presented in separate technical reports.

Sampling Efforts

The utilization of multiple traps beginning in 2002 has improved the ability to generate population estimates due to greater capture efficiency at the site and prevents the loss of catch data for a day if one trap has a flawed set, typically due to becoming clogged with debris. It is recommended that multiple traps continue to be utilized at the lower Trinity River trap site. While trapping operations have been refined to operate the traps at higher flows, $>12,000 \text{ ft}^3/\text{s}$, high and highly variable flows during the beginning of the trapping seasons create challenges in maintaining effective sampling. In 2003 and 2005 a week of

sampling was missed due to high flows and damaged trapping equipment. Missing sampling weeks during these years make it difficult to ascertain emigration timing and peaks.

In most years trapping efforts were initiated in early to mid-March with the exception of 2001, when trapping was initiated in the second week of April. To ensure that the early peak of the natural Chinook salmon emigration, as well as, the hatchery and natural coho salmon and steelhead smolt emigration is sufficiently sampled, efforts should be made to install the traps as early as possible. In some years, the traps were installed after the hatchery release of steelhead and coho salmon, precluding the estimation of emigration period duration and migration rate. In addition to potentially missing parts of the early juvenile salmonid emigration, it is important to initiate sampling as early as possible so that comparable data, especially similar time periods, are collected to allow between year comparisons in emigration timing (duration and peak) and abundance.

Salmonid Biological Information

Chinook salmon were captured throughout the year with the spring emigration dominated by naturally produced fish, comprising 77% to 87% of the spring emigration based on abundance indices. From mid-August to early October very few Chinook salmon were captured. The fall emigration of Chinook salmon occurred over a fairly short period of time, with the peak typically lasting two to three weeks, and was composed of primarily hatchery produced fish (64% to 85%) except in 2003 (46%). Mean length of age-0 Chinook salmon generally increased throughout the spring monitoring period, remained fairly stably from mid-June through July, then gradually increased again. Evaluation of the data on the condition (length-weight) of Chinook salmon outmigrants will be presented in a separate report.

Natural and hatchery produced age-1 coho salmon generally emigrated through the lower Trinity River beginning in early March through early June. Emigration of age-1 coho salmon may occur earlier but trapping is typically initiated in early to mid-March. Based on abundance indices, the age-1 coho salmon emigration is composed of primarily hatchery produced fish, ranging from 58% to 89%. Age-0 coho salmon were captured at the Willow Creek trap site from March to the end of July except in 2001 when no coho salmon were captured after late June. Very few coho salmon of any age were captured after July or during the fall trapping season. While mean length of hatchery and natural age-1 coho salmon was variable within and between years, the mean length of hatchery produced age-1 coho was generally greater than 140mm. The mean length of naturally produced coho salmon was typically less than that of hatchery produced fish except in 2001 when they were generally similar. Mean length of age-0 coho salmon generally increased throughout the sampling season.

The steelhead population in the Trinity River is composed of both tributary and mainstem spawning and rearing populations that exhibit highly variable juvenile life history patterns. Steelhead, especially age-0 and age-1 natural steelhead, were generally

captured throughout the sampling season during all years, with peaks in abundance occurring during the spring portion of the sampling efforts. Age-0 steelhead were captured throughout the sampling season with peaks in abundance occurring in June through July. The majority of age-1 or older natural steelhead generally emigrated by mid-June while the majority of hatchery produced age-1 steelhead emigrated by mid-May. Steelhead mean length data was highly variable, most likely due to the various populations and races being sampled at the Willow Creek trapping site. Mean length of hatchery produced age-1 and age-2 steelhead generally decreased throughout the sampling season except in 2005. Mean length of age-0 and age-1 natural steelhead generally increased throughout the sampling season.

Chinook Salmon Population Estimation

Since 2002, intensive mark-recapture efforts to estimate the size of the emigrating Chinook salmon population, as well as estimating the precision of these estimates, were incorporated into trapping operations. Previous efforts to implement mark-recapture techniques into the trapping efforts were limited due to lack of sufficient funding. Abundance indices based on catches and the proportion of flow sampled by the trap(s) have been the quantification method employed for many years (USFWS 1991, 1994, 1995, 1998, 1999, and 2001) and are generally thought to be adequate indicators of emigration timing and duration if sampling occurred in all weeks of the sampling period. A shortcoming of the abundance indices is that they do not provide a measure of the accuracy of the indices and make inter-year comparisons questionable. Mark-recapture efforts employed since 2002 indicate that precise population estimates can be obtained (95% confidence intervals ranging from +/- 8.9% to 54.9% of the estimate) depending on the proportion of the population marked (marking rate), and capture efficiency (recapture rate).

Low catches early in the sampling season precluded conducting mark-recapture efforts during these periods, therefore the generated estimates only represent times when mark-recapture efforts were conducted. Future efforts should explore the possibility of obtaining hatchery fish in sufficient numbers to estimate capture efficiency during periods when mark-recapture is not feasible. Estimating capture efficiency in periods of low catches would allow calculation of a complete spring season population estimate.

While the magnitude of abundance indices and mark-recapture population estimates are different, the data from 2002 through 2005 for similar time periods indicate that these two measures of population abundance are highly correlated ($r=0.98$), suggesting that abundance indices may be an acceptable surrogate for population abundance. While the relationship between mark-recapture populations estimates and flow based abundance indices is very strong, a larger dataset is necessary to evaluate the strength of this relationship to determine if reducing or eliminating mark-recapture populations efforts is warranted. Additionally, the weakness of the abundance indices is that precision of the estimates cannot be assessed which limits the ability to make between year comparisons of populations estimates. At this time the only measure of coho salmon and steelhead

population size are the flow-based abundance indices. While the relationship between the Chinook salmon mark-recapture populations estimates and flow based abundance indices suggest that the indices may be an acceptable surrogate, it is unknown if this strong correlation applies to coho salmon and steelhead smolts. This is especially important for assessing the magnitude and emigration timing of coho salmon and steelhead populations because there are not sufficient numbers of these species captured to conduct mark-recapture efforts. Additional efforts are needed to assess how a mark-recapture based estimate correlates with a flow based abundance index for these two species.

Future Efforts and Products

The USFWS and YTFP, in cooperation with other TRRP partners, will continue to refine trapping efforts to provide salmonid outmigrant data for use in evaluating the effectiveness of restoration efforts in the Trinity River Basin. Additional reports that are currently under development from data collected by this project include: evaluating the accuracy and precision of population estimates, including addressing periods when mark-recapture techniques cannot be employed; evaluation of the relationship between mark-recapture population estimates and abundance indices; evaluation of outmigrant timing in relation to thermal regimes, and evaluation of outmigrant condition in relation to thermal regimes.
